FINDING ELLIPSES AND HYPERBOLAS TANGENT
TO TWO, THREE, OR FOUR GIVEN LINES

ALAN HORWITZ

Penn State University

5/12/02

ABSTRACT. Given lines L_j, $j = 1, 2, 3, 4$, in the plane, such that no three of the lines are parallel or are concurrent, we want to find the locus of centers of ellipses tangent to the L_j. In the case when the lines form the boundary of a four sided convex polygon R, let M_1 and M_2 be the midpoints of the diagonals of R. Let L be the line thru M_1 and M_2, let Z be the open line segment connecting M_1 and M_2, let Y be the closed line segment connecting M_1 and M_2, and let X be the open line segment which is the part of L lying inside R. It is well known that if an ellipse E is **inscribed** in R, then the center of E must lie on Z(see [1] and [2]). We prove(Theorem 11) that every point of Z is the center of some ellipse inscribed in R, which implies that the locus of centers of ellipses inscribed in R is precisely equal to Z. In addition, we prove(Theorem 11) that there is a hyperbola tangent to each of the L_j and with center $(h, k) \in R$ if and only if $(h, k) \in X - Y$. More generally, any ellipse tangent to the L_j(and not just inscribed ones) must have its center on L.

Introduction

Given finitely lines L_j, $j = 1, 2, 3, ..., N$ in the plane, such that no three of the lines are parallel or are concurrent, we want to find the locus of centers of ellipses tangent to the L_j. Our main results concern four given lines (see §3), though we need results for two or three given tangents (see §1, §2, and §4). Most of the theorems extend easily to hyperbolas as well. It is useful to make the following definition.

Definition. Given a finite set of distinct lines $L_1, L_2, ..., L_N$ in the plane, and an angle α, $-\frac{\pi}{2} < \alpha < \frac{\pi}{2}$, suppose that there is an ellipse with center (h, k) and rotation angle α which is tangent to each of the L_j. Then we say that (h, k) is α **admissible** . If $\alpha = 0$ we just call (h, k) admissible. We allow the angle of rotation to **vary**, and then look at the union, over α, of the α admissible centers, S_α. In the case when the lines form the boundary of a four sided convex polygon R, let M_1 and M_2 be the midpoints of the diagonals of R. Let L be the line thru M_1 and M_2, let Z be the open line segment connecting M_1 and M_2, let X be the open line segment which is the part of L lying inside R, and let Y equal the **closed** line segment connecting M_1 and M_2. It is well known that if an ellipse E is **inscribed**

---

in R, then the center of E must lie on Z(see [1] and [2]). We prove the stronger result(Theorem 11) that there is an ellipse inscribed in R with center (h, k) if and only if $(h, k) \in Z$. In addition, we prove(Theorem 11) that there is a hyperbola tangent to each of the L_j and with center $(h, k) \in R$ if and only if $(h, k) \in X - Y$.
Remark : Due to a miscommunication the paper "Finding an Ellipse Tangent to finitely many given Lines"[3], which appeared in SWJPM in December of 2000, was not the final version to be published. Section 2 is a modification and simplification of results which appeared in [3]. Section 4 contains a simplified and abridged version of material which appeared in [3]. It also contains corrections for numerous errors in the original version. All of our results in Section 3 for four given tangents are new.

§1. Preliminary Material

Our results are stated and proved first for ellipses with major and minor axes parallel to the x and y axes. Later we indicate how to extend the results easily to rotated ellipses. We use the fact that at any point of the ellipse $\dfrac{(x - h)^2}{a^2} + \dfrac{(y - k)^2}{b^2} = 1$, $dy/dx = \left(-\dfrac{b^2}{a^2}\right)\left(\dfrac{x - h}{y - k}\right)$.

Lemma 1. Let (h, k) be given. Suppose that L is a non-vertical line with equation $y - k = m(x - h) + B$

(i) If (u, v) is a **positive** solution of the equation $m^2 u + v = B^2$, then $B \neq 0$, and L is tangent to the ellipse $\dfrac{(x - h)^2}{a^2} + \dfrac{(y - k)^2}{b^2} = 1$ at (r, s), where $a^2 = u, b^2 = v$, $r = h - \dfrac{a^2 m}{B}$, and $s = k + \dfrac{b^2}{B}$.

(ii) If L is tangent to the ellipse E: $\dfrac{(x - h)^2}{a^2} + \dfrac{(y - k)^2}{b^2} = 1$ at (r, s), then $B \neq 0, s \neq k$, and $m^2 a^2 + b^2 = B^2$.

Proof. Since $u, v > 0$, $B \neq 0$. $\dfrac{(r - h)^2}{a^2} + \dfrac{(s - k)^2}{b^2} = \dfrac{a^2 m^2 + b^2}{B^2} = 1$ and $m(r - h) + B = m\left(-\dfrac{a^2 m}{B}\right) + B = \dfrac{-a^2 m^2 + B^2}{B} = \dfrac{b^2}{B} = s - k$. Thus (r, s) lies on both E and L. Note that $s \neq k$, and since $B \neq 0, \dfrac{r - h}{s - k} = \dfrac{-a^2 m}{b^2}$. Thus $\left[\dfrac{dy}{dx}\right]_{x=r,y=s} = \dfrac{-b^2(r - h)}{a^2(s - k)} = m$, and L is tangent to E at (r, s), which proves (i).
If $B = 0$, then L passes thru (h, k), which is impossible if L is tangent to an ellipse with center (h, k). If $s = k$, then L is vertical. Since $dy/dx = \left(-\dfrac{b^2}{a^2}\right)\left(\dfrac{x - h}{y - k}\right)$ at any point of $E(y \neq k)$, we have

$$(1) \qquad\qquad m = -\frac{b^2}{a^2}\frac{r - h}{s - k}$$

Also,

$$(2) \qquad\qquad s - k = m(r - h) + B$$

2

Using (1) and substituting (2) gives $a^2 m\,(m(r-h)+B) + b^2(r-h) = 0$, which implies

(3)
$$r = h - \frac{a^2 m B}{a^2 m^2 + b^2}$$

By (2) we also have

(4)
$$s = k + \frac{b^2 B}{a^2 m^2 + b^2}$$

(3), (4), and $\dfrac{(r-h)^2}{a^2} + \dfrac{(s-k)^2}{b^2} = 1$ imply that $\dfrac{a^2 m^2 B^2 + b^2 B^2}{(a^2 m^2 + b^2)^2} = 1$, which implies that $B^2 = a^2 m^2 + b^2$. That proves (ii). ∎

Proposition 1. Suppose that L_1 and L_2 are non-vertical lines which are tangent to the ellipse $\dfrac{(x-h)^2}{a^2} + \dfrac{(y-k)^2}{b^2} = 1$ at (r_j, s_j), $j = 1, 2$. Suppose that L_j has equation

(5)
$$y - k = m_j(x-h) + b_j$$

$j = 1, 2$, with $m_1^2 \neq m_2^2$. Then

(6)
$$a^2 = \frac{b_2^2 - b_1^2}{m_2^2 - m_1^2}, \quad b^2 = \frac{b_1^2 m_2^2 - b_2^2 m_1^2}{m_2^2 - m_1^2}$$

Proof. By Lemma 1, part (ii), $a^2 = u$ and $b^2 = v$, where u and v satisfy the **nonsingular** linear system

(7)
$$m_1^2 u + v = b_1^2$$
$$m_2^2 u + v = b_2^2$$

Substituting back for the unique solution (u, v) yields (6). ∎

Remark. Throughout the paper we suppress, in our notation, the fact that if $y = L_j(x) = m_j x + c_j$ and $y - k = m_j(x-h) + b_j$ represent the same line, then

(8)
$$b_j = L_j(h) - k = m_j h + c_j - k$$

is really a function of h and k.

Theorem 1. Let h and k be given real numbers, and let L_1 and L_2 be distinct, non–vertical lines with equations $y - k = m_j(x-h) + b_j$, $j = 1, 2$, $m_1^2 \neq m_2^2$.
Part 1: If

(9)
$$\frac{b_2^2 - b_1^2}{m_2^2 - m_1^2} > 0 \text{ and } \frac{b_1^2 m_2^2 - b_2^2 m_1^2}{m_2^2 - m_1^2} > 0$$

3

then there is a unique ellipse E(non-rotated), with center (h, k), which has L_1 and L_2 as tangents. Furthermore, E has equation $\dfrac{(x-h)^2}{a^2} + \dfrac{(y-k)^2}{b^2} = 1$, where a^2 and b^2 are given by (6).

Part 2: (9) is also a *necessary* condition for L_1 and L_2 to be tangent to some ellipse(non-rotated), with center (h, k).

Proof. Part 1: Since (9) holds, (7) has the unique positive solution (u, v) with $u = a^2$ and $v = b^2$, a^2 and b^2 defined as in (6). By Lemma 1, part (i), the L_j are tangent, at (r_j, s_j), to the ellipse E with equation $\dfrac{(x-h)^2}{a^2} + \dfrac{(y-k)^2}{b^2} = 1$, where $r_j = h - \dfrac{a^2 m_j}{b_j}$ and $s_j = k + \dfrac{b^2}{b_j}$. Now if $\tilde{E}$ is *any* ellipse with center (h, k) and tangent to the L_j, then the equation of $\tilde{E}$ is $\dfrac{(x-h)^2}{\tilde{a}^2} + \dfrac{(y-k)^2}{\tilde{b}^2} = 1$. By Proposition 1, $\tilde{a}$ and $\tilde{b}$ are given by (6), which implies that $\tilde{a} = a^2$ and $\tilde{b}^2 = b^2$. That proves uniqueness.

Part 2: Follows immediately from Proposition 1. ∎

Given L_1 and L_2, we can now give an equivalent characterization of the set of admissible centers.

Corollary 1. Let $y = L_1(x)$ and $y = L_2(x)$ be distinct, non–vertical lines with equations $y = L_j(x) = k + m_j(x - h) + b_j, j = 1, 2$ and $|m_1| < |m_2|$. Then there is an ellipse E(non-rotated) with center (h, k), which has L_1 and L_2 as tangents if and only if

$$\text{(10)} \qquad \left|\frac{m_1}{m_2}\right| |b_2| < |b_1| < |b_2|$$

or equivalently

$$\text{(11)} \qquad \left|\frac{m_1}{m_2}\right| < \left|\frac{L_1(h) - k}{L_2(h) - k}\right| < 1$$

Proof. Since $|m_1| < |m_2|$, (10) is equivalent to (9). Since $b_j = L_j(h) - k$, (10) is equivalent to (11) and the fact that $b_2 \neq 0 \Leftrightarrow L_2(h) - k \neq 0$. ∎

Example. $L_1 : \ y = x + 3$ and $L_2 : \ y = 2x - 3$ are given. Then L_1 and L_2 are tangents to a non-rotated ellipse E with center (h, k) if and only if $\dfrac{1}{2} < \left|\dfrac{h + 3 - k}{2h - 3 - k}\right| < 1$.

Remark. One can also obtain results similar to Proposition 1 or Theorem 1 if one of the L_j(but not **both**) is *vertical* . If L_1 has equation $x - h = b_1$, then $b_1 = a$ or $-a$, which implies that $a^2 = b_1^2$. Since $m_2^2 a^2 + b^2 = b_2^2$ still holds, one then solves to get b^2.

We shall have occasion to use the following theorem, which follows immediately from Lemma 1, Proposition 1, and Theorem 1.

4

Theorem 2. Given N non-vertical lines $L_1, ..., T_N$ with equations $y - k = m_j(x - h) + b_j$, $j = 1, ..., N$.
(i) There is an ellipse E(non-rotated), with center (h, k), tangent to each of the L_j if and only if the linear system

(12)
$$m_1^2 u + v = b_1^2$$
$$m_2^2 u + v = b_2^2$$
$$\vdots$$
$$m_N^2 u + v = b_N^2$$

has a **positive** solution (u, v). If $m_i^2 \neq m_j^2$ whenever $i \neq j$, then E is unique and has equation $\dfrac{(x-h)^2}{a^2} + \dfrac{(y-k)^2}{b^2} = 1$, where $a^2 = u$ and $b^2 = v$.
(ii) If $m_i^2 \neq m_j^2$ whenever $i \neq j$ and (12) is consistent, then for any $i \neq j$, the unique solution of (12) is

(13)
$$u = \frac{b_j^2 - b_i^2}{m_j^2 - m_i^2} \text{ and } v = \frac{b_i^2 m_j^2 - b_j^2 m_i^2}{m_j^2 - m_i^2}$$

Remark. If $m_1^2 = m_2^2$, then the existence-uniqueness result above fails. We discuss this for two given lines in the next theorem.

Theorem 3. Let h and k be given real numbers, and let L_1 and L_2 be distinct, non–vertical lines with equations $y - k = m_j(x - h) + b_j$, $j = 1, 2$. Suppose that $m_1^2 = m_2^2$.
(i) If $|b_1| = |b_2| \neq 0$, then L_1 and L_2 are tangent to any ellipse $E \in F = \left\{ \dfrac{(x-h)^2}{a^2} + \dfrac{(y-k)^2}{b^2} = 1 \right\}$, where a^2 and b^2 are any positive real numbers satisfying the equation

(14)
$$a^2 m_1^2 + b^2 = b_1^2$$

(ii) If $|b_1| \neq |b_2|$ or $b_1 = 0 = b_2$, then L_1 and L_2 are not tangent to any ellipse(non-rotated) with center (h, k).
Proof. Since the line with equation $m_1^2 u + v = b_1^2$ has a positive v intercept and a non-positive slope, $m_1^2 u + v = b_1^2$ has infinitely many positive solutions in the unknowns u and v. If $a^2 = u, b^2 = v$ for some positive solution (u, v), then (14) holds. Also, $a^2 m_2^2 + b^2 = b_2^2$ since $m_1^2 = m_2^2$ and $b_1^2 = b_2^2$. (i) then follows from Lemma 1, part (i). To prove (ii), suppose that L_1 and L_2 are tangent to an ellipse E with equation $\dfrac{(x-h)^2}{a^2} + \dfrac{(y-k)^2}{b^2} = 1$. By Lemma 1, part (ii), $b_j^2 = a^2 m_j^2 + b^2$, $j = 1, 2$. Lemma 1, part (ii), $m_1^2 = m_2^2$,, and $b_1^2 = b_2^2$, then imply that $b_1^2 \neq 0 \neq b_2^2$. That contradicts the assumptions in (ii). ∎

Rotated Ellipses

For simplicity of exposition, we have only considered non-rotated ellipses. However, the previous results extend with little effort to ellipses whose axes are *rotated* clockwise about $(0,0)$ thru a specified angle α, $-\dfrac{\pi}{2} < \alpha < \dfrac{\pi}{2}$. Let (x_α, y_α) denote the new coordinates, and suppose that we are given (h, k) in xy coordinates. Assume throughout that no given line is parallel to the y_α axis(i.e., all lines are non–vertical in the rotated coordinates). It follows easily that the line $y - k = m(x - h) + b$ becomes

$$(15) \qquad y_\alpha - k_\alpha = \left(\frac{m + \tan\alpha}{1 - m\tan\alpha} \right)(x_\alpha - h_\alpha) + \frac{b\sec\alpha}{1 - m\tan\alpha}$$

where $h_\alpha = h\cos\alpha - k\sin\alpha$, $k_\alpha = h\sin\alpha + k\cos\alpha$ and $1 - m\tan\alpha \neq 0$. We find it useful to introduce the following notation. For given $m_{i,\alpha}, b_{i,\alpha}, m_{j,\alpha}, b_{j,\alpha}$, and α:

$$(16) \qquad S_{ij} = \frac{b_{j,\alpha}^2 - b_{i,\alpha}^2}{m_{j,\alpha}^2 - m_{i,\alpha}^2}, \, T_{ij} = \frac{b_{i,\alpha}^2 m_{j,\alpha}^2 - b_{j,\alpha}^2 m_{i,\alpha}^2}{m_{j,\alpha}^2 - m_{i,\alpha}^2}$$

We now state the following generalization of Theorem 1 without proof.

Theorem 4. Let h_α and k_α be given real numbers, and let L_1 and L_2 be distinct lines with equations $y_\alpha - k_\alpha = m_{j,\alpha}(x_\alpha - h_\alpha) + b_{j,\alpha}$, $j = 1, 2$. Suppose that $m_{2,\alpha}^2 \neq m_{1,\alpha}^2$.
Part 1: If

$$(17) \qquad\qquad\qquad S_{12} > 0 \text{ and } T_{12} > 0$$

then there is a unique ellipse E, with equation $\dfrac{(x_\alpha - h_\alpha)^2}{a^2} + \dfrac{(y_\alpha - k_\alpha)^2}{b^2} = 1$, which has L_1 and L_2 as tangents, where $a^2 = S_{12}$ and $b^2 = T_{12}$
Part 2: (17) is also a *necessary* condition for L_1 and L_2 to be tangent to some ellipse with center (h, k) and rotation angle α.
Remark. As in the non-rotated case, if $|m_{1,\alpha}| < |m_{2,\alpha}|$, then (17) is equivalent to

$$(18) \qquad\qquad \left| \frac{m_{1,\alpha}}{m_{2,\alpha}} \right| |b_{2,\alpha}| < |b_{1,\alpha}| < |b_{2,\alpha}|$$

It is also interesting to allow the rotation angle to *vary*. This leads to the following
Question: Let L_1 and L_2 be two given nonparallel lines. Is any point $(h, k) \notin L_1 \cup L_2$ α admissible for some α, $-\dfrac{\pi}{2} < \alpha < \dfrac{\pi}{2}$? The following theorem answers this question in the affirmative.

Theorem 5. Let h and k be given real numbers, and let L_1 and L_2 be distinct, non–vertical lines with equations $y - k = m_j(x - h) + b_j$, $j = 1, 2$. Assume that $m_1 \neq m_2$ and that $(h, k) \notin L_1 \cup L_2$. Then there is an angle α, $-\dfrac{\pi}{2} < \alpha < \dfrac{\pi}{2}$, such that the ellipse E with center (h, k) and rotation angle α has L_1 and L_2 as tangents.

6

Proof. Note that $(h, k) \notin L_1 \cup L_2 \Rightarrow b_1 \neq 0 \neq b_2$. We want to apply (10) of Corollary 1 in the *new* coordinates x_α and y_α. Using (15), we replace m_j by $m_{j,\alpha}$ and b_j by $b_{j,\alpha}$, where $m_{j,\alpha} = \dfrac{m_j + \tan \alpha}{1 - m_j \tan \alpha}$ and $b_{j,\alpha} = \dfrac{b_j \sec \alpha}{1 - m_j \tan \alpha}$ Since we are allowing the angle of rotation to vary, we may rotate the coordinate axes so that in the new coordinates, $m_1 = 0 < m_2$. Then $\left| \dfrac{m_1}{m_2} \right| |b_2| < |b_1|$. If $|b_1| < |b_2|$, then by the corollary to Theorem 1, there is a non-rotated ellipse tangent to the L_j. So assume now that $|b_2| \leq |b_1|$, and let $\alpha_0 = \arctan(1/m_2)$. Note that $\dfrac{m + \tan \alpha}{1 - m \tan \alpha}$ is a strictly increasing function of m, which implies that $m_{1,\alpha} < m_{2,\alpha}$ for any given α. As $\alpha \to \alpha_0$, $\dfrac{|b_{1,\alpha}|}{|m_{1,\alpha}|} = \left| \dfrac{b_1 \sec \alpha}{\tan \alpha} \right| \to \left| \dfrac{b_1 \sec \alpha_0}{\tan \alpha_0} \right| = |b_1| \sqrt{1 + m_2^2}$, and $\dfrac{|b_{2,\alpha}|}{|m_{2,\alpha}|} = \left| \dfrac{b_2 \sec \alpha}{m_2 + \tan \alpha} \right| \to \left| \dfrac{b_2 \sec \alpha_0}{m_2 + \tan \alpha_0} \right| = \dfrac{|b_2|}{\sqrt{1 + m_2^2}}$. Note that $\tan \alpha_0 = \dfrac{1}{m_2} \Rightarrow m_2 + \tan \alpha_0 \neq 0$. Now $\dfrac{|b_{2,\alpha}|}{|m_{2,\alpha}|} < \dfrac{|b_{1,\alpha}|}{|m_{1,\alpha}|}$ if and only if $\dfrac{|b_2|}{\sqrt{1 + m_2^2}} < |b_1| \sqrt{1 + m_2^2}$ if and only if $\left| \dfrac{b_2}{b_1} \right| < 1 + m_2^2$, which holds since $\left| \dfrac{b_2}{b_1} \right| \leq 1 < 1 + m_2^2$. Also, $\lim\limits_{\alpha \to \alpha_0} |b_{2,\alpha}| = \lim\limits_{\alpha \to \alpha_0} \left| \dfrac{b_2 \sec \alpha}{1 - m_2 \tan \alpha} \right| = \infty$, while $\lim\limits_{\alpha \to \alpha_0} |b_{1,\alpha}| = \lim\limits_{\alpha \to \alpha_0} |b_1 \sec \alpha| \neq \infty$. Thus for α sufficiently close to α_0, $\left| \dfrac{m_{1,\alpha}}{m_{2,\alpha}} \right| |b_{2,\alpha}| < |b_{1,\alpha}| < |b_{2,\alpha}|$, and the theorem follows from the remark after Theorem 4. ∎

An Aside on Hyperbolas
For **hyperbolas** rather than ellipses tangent to L_1 and L_2, one would want a solution of (7) with $uv < 0$. In Lemma 1, part (ii), if T is tangent to the hyperbola $H : \dfrac{(x - h)^2}{a^2} - \dfrac{(y - k)^2}{b^2} = \pm 1$ at (r, s), then $B \neq 0, s \neq k$, and $m^2 a^2 - b^2 = \pm B^2$. It then follows that a necessary and sufficient condition to have a hyperbola tangent to L_1 and L_2 is $\dfrac{b_2^2 - b_1^2}{m_2^2 - m_1^2} \dfrac{b_1^2 m_2^2 - b_2^2 m_1^2}{m_2^2 - m_1^2} < 0$. A version of Theorem 4 for hyperbolas follows immediately.

Theorem 6. Let h_α and k_α be given real numbers, and let L_1 and L_2 be distinct lines with equations $y_\alpha - k_\alpha = m_{j,\alpha}(x_\alpha - h_\alpha) + b_{j,\alpha}$, $j = 1, 2$. Assume that $m_{2,\alpha}^2 \neq m_{1,\alpha}^2$.
Part 1: If

$$(19) \qquad\qquad S_{12} T_{12} < 0$$

then there is a unique hyperbola H, with center (h, k) and rotation angle α, which has L_1 and L_2 as tangents.
Part 2: (19) is also a *necessary* condition for a hyperbola with center (h, k) and rotation angle α to exist which has L_1 and L_2 as tangents.

7

§2 Rotated Versions of Key Theorems from §1

Assume throughout, unless stated otherwise, that no given line is parallel to the y_α axis. The line L_j with equation $y = m_j x + c_j$ becomes

$$(20) \qquad y_\alpha = m_{j,\alpha} x_\alpha + c_{j,\alpha}$$

where

$$(21) \qquad m_{j,\alpha} = \frac{m_j + \tan\alpha}{1 - m_j \tan\alpha} \text{ and } c_{j,\alpha} = \frac{c_j \sec\alpha}{1 - m_j \tan\alpha}$$

$1 - m_j \tan\alpha \neq 0$. Rewrite L_j in the form

$$(22) \qquad y_\alpha - k_\alpha = m_{j,\alpha}(x_\alpha - h_\alpha) + b_{j,\alpha}, b_{j,\alpha} = m_{j,\alpha} h_\alpha + c_{j,\alpha} - k_\alpha$$

In xy coordinates, $h_\alpha = h\cos\alpha - k\sin\alpha$ and $k_\alpha = h\sin\alpha + k\cos\alpha$ for some real numbers h and k. Dividing thru by $\cos\alpha$ and using the substitution

$$w = \tan\alpha$$

yields

$$(23) \qquad h_\alpha = \frac{1}{\sqrt{1 + w^2}}(h - kw), k_\alpha = \frac{1}{\sqrt{1 + w^2}}(hw + k)$$

which gives

$$(24) \qquad b_{j,\alpha} = \frac{m_{j,\alpha}}{\sqrt{1 + w^2}}(h - kw) + c_{j,\alpha} - \frac{1}{\sqrt{1 + w^2}}(hw + k)$$

We shall always speak of α admissible centers in xy coordinates. Throughout, given $L_1, ..., L_N$, $\Re_\alpha$ denotes the set of α admissible centers, i.e., the set of all (h, k) such that the ellipse, $\dfrac{(x_\alpha - h_\alpha)^2}{a^2} + \dfrac{(y_\alpha - k_\alpha)^2}{b^2} = 1$, is tangent to each of the L_j. If L_i and L_j are not parallel, we let $i(L_i, L_j) = (x_{l,\alpha}, y_{l,\alpha}), i \neq l \neq j$ denote their point of intersection(in rotated coordinates). Theorems 14-17(proved in §4) and Theorem 2 are easily extendable to rotated ellipses, which we state here.

Theorem 7. Suppose one is given N lines $L_1, ..., L_N$ with equation given by (22) and an angle $\alpha, -\dfrac{\pi}{2} < \alpha < \dfrac{\pi}{2}$. Then
(i) There is an ellipse E with center (h, k) and rotation angle α tangent to each of the L_j if and only if the linear system

$$(25) \qquad \begin{aligned} m_{1,\alpha}^2 u + v &= b_{1,\alpha}^2 \\ m_{2,\alpha}^2 u + v &= b_{2,\alpha}^2 \\ &\vdots \\ m_{N,\alpha}^2 u + v &= b_{N,\alpha}^2 \end{aligned}$$

8

has a positive solution (u, v). If $m_{i,\alpha}^2 \neq m_{j,\alpha}^2$ whenever $i \neq j$, then E is unique and the equation of E in the new rotated coordinates is $\dfrac{(x_\alpha - h_\alpha)^2}{a^2} + \dfrac{(y_\alpha - k_\alpha)^2}{b^2} = 1$, where $a^2 = u$ and $b^2 = v$. (ii) If $m_{i,\alpha}^2 \neq m_{j,\alpha}^2$ whenever $i \neq j$ and (25) is consistent, then for any $i \neq j$, the unique solution of (25) is (see (16))

(26) $$u = S_{ij} \text{ and } v = T_{ij}$$

Expanding the determinants and the left-hand side of (36) in Theorem 12 yields

Theorem 8. Let L_j, $j = 1, 2, 3$, be distinct, non-concurrent lines with equations given by (20), $i \neq j \Rightarrow m_{i,\alpha}^2 \neq m_{j,\alpha}^2$. Let $d_\alpha = \prod\limits_{j>i} (m_{j,\alpha} - m_{i,\alpha})$,

$a_{1,\alpha} = m_{1,\alpha} c_{1,\alpha} \left(m_{3,\alpha}^2 - m_{2,\alpha}^2 \right) - m_{2,\alpha} c_{2,\alpha} \left(m_{3,\alpha}^2 - m_{1,\alpha}^2 \right) + m_{3,\alpha} c_{3,\alpha} \left(m_{2,\alpha}^2 - m_{1,\alpha}^2 \right)$,
$a_{2,\alpha} = -c_{1,\alpha} \left(m_{3,\alpha}^2 - m_{2,\alpha}^2 \right) + c_{2,\alpha} \left(m_{3,\alpha}^2 - m_{1,\alpha}^2 \right) - c_{3,\alpha} \left(m_{2,\alpha}^2 - m_{1,\alpha}^2 \right)$,
$a_{3,\alpha} = (c_{1,\alpha}^2 (m_{3,\alpha}^2 - m_{2,\alpha}^2) - c_{2,\alpha}^2 (m_{3,\alpha}^2 - m_{1,\alpha}^2) + c_{3,\alpha}^2 (m_{2,\alpha}^2 - m_{1,\alpha}^2))/2$.
Then (25), with $N = 3$, has a unique solution if and only if (h_α, k_α) lies on the curve γ with equation

(27) $$d_\alpha h_\alpha k_\alpha + a_{1,\alpha} h_\alpha + a_{2,\alpha} k_\alpha + a_{3,\alpha} = 0$$

Theorem 9. Let L_1 and L_2 be distinct lines with equations given by (20), $0 \neq m_{1,\alpha}^2 \neq m_{2,\alpha}^2$. Let L_3 be the line with equation $x_\alpha = c_{3,\alpha}$. Let γ be the curve with equation
$(h_\alpha - x_{3,\alpha})(k_\alpha - a_{1,\alpha}) = -\frac{1}{2} (m_{1,\alpha} + m_{2,\alpha})(c_{3,\alpha} - x_{3,\alpha})^2$, where
$a_{1,\alpha} = L_2(c_{3,\alpha}) + L_1(c_{3,\alpha}) - y_{3,\alpha}$. Let $q_3(k_\alpha) = \prod\limits_{j=1}^{3} (k_\alpha - y_{j,\alpha})$,

$q_1(k_\alpha) = m_{1,\alpha}^2 (k_\alpha - a_{1,\alpha})$. Then $(h, k) \in \Re_\alpha \Leftrightarrow (h_\alpha, k_\alpha) \in \gamma$, $h_\alpha \neq c_{3,\alpha}$ and $\dfrac{q_3(k_\alpha)}{q_1(k_\alpha)} > 0$. For each $(h, k) \in \Re_\alpha$, there is a unique ellipse E with equation $\dfrac{(x_\alpha - h_\alpha)^2}{a^2} + \dfrac{(y_\alpha - k_\alpha)^2}{b^2} = 1$ which is tangent to each of the L_j, with $a^2 = (h_\alpha - c_{3,\alpha})^2$ and $b^2 = \dfrac{q_3(k_\alpha)}{q_1(k_\alpha)}$.

§3 Main Results for Four Given Tangents

We now discuss the locus of centers of ellipses tangent to **four** given lines, where the angle of rotation is allowed to vary. In particular, using the methods of this paper we are able to strengthen and extend some known results about ellipses inscribed in quadrilaterals. Given four lines in the plane, L_j, $j = 1, 2, 3, 4$, such that no three of the lines are parallel or are concurrent, we want to find the locus of centers of ellipses tangent to the lines. In the case when the lines form the boundary of a four sided convex polygon R, let M_1 and M_2 be the midpoints of the diagonals of R. Let L be the line thru M_1 and M_2, let Z be the open line segment connecting M_1 and M_2, let Y be the **closed** line segment connecting M_1 and M_2, and let X

9

be the open line segment which is the part of L lying inside R. It is well known that if an ellipse E is **inscribed** in R, then the center of E must lie on Z(see [1] and [2]). The proof of this result actually goes back to Newton. It is stated in [2] that the locus of centers of ellipses inscribed in R actually **equals** Z, but Newton only proved that the center of E must lie on Z, as is noted in [1]. Indeed, it is not even clear that an ellipse even **exists** which is inscribed in R, let alone whether **every point** of Z is the center of such an ellipse. We prove(Theorem 11) that every point of Z is the center of some ellipse inscribed in R, which implies that the locus of centers of ellipses inscribed in R is precisely equal to Z. In addition, we prove (Theorem 11) that there is a hyperbola tangent to each of the L_j and with center $(h, k) \in R$ if and only if $(h, k) \in X - Y$. More generally, any ellipse tangent to the L_j(and not just inscribed ones) must have its center on L.

Theorem 11. Let R be a four sided **convex** polygon in the xy plane which is not a parallelogram, and let M_1 and M_2 be the midpoints of the diagonals of R. Let L be the line thru M_1 and M_2, and let L_j, $j = 1, 2, 3, 4$ denote the lines which make up the boundary of R. Let Z be the open line segment connecting M_1 and M_2, let X be the open line segment which is the part of L lying inside R, and let Y equal the **closed** line segment connecting M_1 and M_2.
(i) If an ellipse E or hyperbola H is tangent to each of the L_j, then the center of E or of H must lie on L.
(ii) There is an ellipse E, **inscribed** in R and with center (h, k), if and only if $(h, k) \in Z$.
(iii) There is a hyperbola tangent to each of the L_j and with center $(h, k) \in R$, if and only if $(h, k) \in X - Y$.
Remark. If R is a parallelogram, then an ellipse E which is inscribed in R must have center equal to the center of R. There is no hyperbola tangent to each of the L_j and with center $(h, k) \in R$.
Proof. We shall assume that no two sides of R are parallel. The proof when at least two sides of R are parallel is similar, but somewhat simpler, than the proof given here. By using an affine transformation, we may assume that the vertices of R are $(0, 0), (1, 0), (0, 1)$, and (s, t) for some real numbers s and t. Since R is convex, it follows easily that

$$s > 0, t > 0 \text{ and } s + t \geq 1$$

Since R is four sided and no two sides of R are parallel,

$$s + t > 1 \text{ and } s \neq 1 \neq t$$

Write $L_1 : y = 0, L_2 : x = 0, L_3 : y = 1 + \left(\dfrac{t-1}{s}\right)x, L_4 : y = \dfrac{t}{s-1}(x - 1)$. For fixed α, (21) gives $m_{1,\alpha} = w$, $m_{3,\alpha} = \dfrac{t - 1 + ws}{s - (t-1)w}$, $m_{4,\alpha} = \dfrac{t + w(s-1)}{s - 1 - wt}$, $c_{1,\alpha} = 0$, $c_{3,\alpha} = \dfrac{s\sqrt{1 + w^2}}{s - (t-1)w}$, $c_{4,\alpha} = -t\dfrac{\sqrt{1 + w^2}}{s - 1 - wt}$. The equation of L_2 in x_α and y_α coordinates is given by (20), with $m_{2,\alpha} = -\dfrac{1}{w}$ and $c_{2,\alpha} = 0$. Writing L_j in the form

10

$y_\alpha - k_\alpha = m_{j,\alpha}(x_\alpha - h_\alpha) + b_{j,\alpha}$ yields, by (24), $b_{1,\alpha} = -k\sqrt{1+w^2}$,

$b_{2,\alpha} = -h\dfrac{\sqrt{1+w^2}}{w}$, $b_{3,\alpha} = \dfrac{((t-1)h - (k-1)s)\,w^2 + (t-1)h - (k-1)s}{(s-(w-1)t)\sqrt{1+w^2}}$,

$b_{4,\alpha} = \dfrac{(t(h-1) - k(s-1))\,w^2 + t(h-1) - k(s-1)}{(s-1-wt)\sqrt{1+w^2}}$. In general,

$m_{j,\alpha}^2 - m_{i,\alpha}^2 = c_{i,j}\left(1+w^2\right)\dfrac{p_{i,j}(w)}{q_{i,j}(w)}$, where the $c_{i,j}$ are nonzero constants depending on s and t, and $p_{i,j}$ and $q_{i,j}$ are polynomials depending on s and t, with $\deg p_{i,j} = 2$ and $\deg q_{i,j} \le 4$. In particular, $m_{2,\alpha}^2 - m_{1,\alpha}^2 = \dfrac{1-w^4}{w^2}$. Now $m_{j,\alpha}$ and $c_{j,\alpha}$ are not defined, for $j \ge 2$, when

$$w \in F_1 = \{0, \frac{s}{t-1}, \frac{s-1}{t}\}$$

Let

$$F_2 = \{w : m_{j,\alpha}^2 - m_{i,\alpha}^2 = 0 \text{ for some } i \ne j\}$$

and let

$$F = F_1 \cup F_2, G = \{w : -\infty < w < \infty\} - F$$

We must assume, for now, that $w \in G$, and in particular we want $m_{j,\alpha}^2 - m_{i,\alpha}^2 \ne 0$ so that we can apply Theorem 8. For s and t given, F is a *finite* set. By Theorem 8, applied to L_1, L_2, L_4 and L_2, L_3, L_4, respectively, if $w \in G$, then an admissible center (h, k) must lie on the curves with equations

(28) $$d_\alpha h_\alpha k_\alpha + a_{1,\alpha} h_\alpha + a_{2,\alpha} k_\alpha + a_{3,\alpha} = 0$$

and

(29) $$D_\alpha h_\alpha k_\alpha + A_{1,\alpha} h_\alpha + A_{2,\alpha} k_\alpha + A_{3,\alpha} = 0$$

where $m_{4,\alpha}$ replaces $m_{3,\alpha}$ when Theorem 8 is applied to $L_1, L_2,$ and L_4, and $m_{4,\alpha}$ replaces $m_{1,\alpha}$ when Theorem 8 is applied to $L_2, L_3,$ and L_4. In (29) we used capital letters to better distinguish the two equations. Using (23), we can rewrite (28) and (29) in the original xy coordinate system to obtain

(30) $$d_\alpha \frac{1}{1+w^2}(h-kw)(hw+k) + a_{1,\alpha}\frac{1}{\sqrt{1+w^2}}(h-kw) + a_{2,\alpha}\frac{1}{\sqrt{1+w^2}}(hw+k) + a_{3,\alpha} = 0$$

and

(31) $$D_\alpha \frac{1}{1+w^2}(h-kw)(hw+k) + A_{1,\alpha}\frac{1}{\sqrt{1+w^2}}(h-kw) + A_{2,\alpha}\frac{1}{\sqrt{1+w^2}}(hw+k) + A_{3,\alpha} = 0$$

Note that d_α and D_α have the factor $m_{4,\alpha} - m_{2,\alpha}$ in common. Thus multiplying (30) by $(m_{4,\alpha} - m_{3,\alpha})(m_{3,\alpha} - m_{2,\alpha})$, multiplying (31) by $(m_{4,\alpha} - m_{1,\alpha})(m_{2,\alpha} - m_{1,\alpha})$, and subtracting yields

$$\left(1+w^2\right)^4 st(t-1+s)(w^2(s-1)+2wt-w^2+1)\frac{2k(s-1)-2h(t-1)-(s-t)}{2(s-w(t-1))^2 w^3(s-1-wt)^3} = 0$$

which implies that $2k(s-1) - 2h(t-1) - (s-t) = 0$, or

$$(32) \qquad\qquad k = L(h) = \frac{1}{2}\frac{s - t + 2h(t-1)}{s-1}$$

Now $M_1 = \left(\frac{1}{2}, \frac{1}{2}\right)$ and $M_2 = \left(\frac{1}{2}s, \frac{1}{2}t\right)$, so that $L(x)$ from (32) is the line L thru M_1 and M_2. Note that the **same equations** must be satisfied in order to have a **hyperbola** tangent to all four lines. Also, while we have assumed that $w \in G$, (32) actually holds for any $w \in (-\infty, \infty)$. One can prove this directly for $w \in F_1$ using Theorem 9. It also follows easily that for any given w, there is *at most one* pair $i \neq j$ with $m_{j,\alpha}^2 - m_{i,\alpha}^2 = 0$. One can then choose two sets of three of the L_j so that L_i and L_j never appear in the same set. (32) can then be derived in the same way as above. That proves (i). We now attempt to solve (30) with $k = L(h)$.

First, the LHS of (30) factors into $\dfrac{1}{4}\dfrac{\left(1+w^2\right)^2 t}{w^2 \left(s-1-tw\right)^2 (s-1)} P(w,h)$, where

$$P(w,h) = A(h)w^2 + B(h)w - A(h)$$

$A(h) = 2\left(s-1\right)\left(\left(2t-2\right)h^2 + \left(s+2-t\right)h - s\right)$ and
$B(h) = \left(1-2h\right)\left(s-t\right)\left(\left(2s-4+2t\right)h + s - t\right)$. Of course the coefficients of $P(w,h)$ depend on s and t as well, but we suppress that in our notation.

Claim: If $k = L(h)$, then $A(h)$ and $B(h)$ cannot both be 0 for the same value of h.

Proof of Claim: Suppose that $A(h_0) = B(h_0) = 0$ for some h_0. Now $B(h_0) = 0$ if and only if $h_0 = \dfrac{1}{2}$ or $h_0 = \dfrac{1}{2}\dfrac{t-s}{s+t-2}$. If $h_0 = \dfrac{1}{2}$, then $(2t-2) h_0^2 + (s+2-t) h_0 - s = \dfrac{1}{2} - \dfrac{1}{2}s \neq 0$ since $s \neq 1$. If $h_0 = \dfrac{1}{2}\dfrac{t-s}{s+t-2}$, then $k_0 = L(h_0) = \dfrac{1}{2}\dfrac{s-t}{s-2+t} = -h_0$, which implies that h_0 and k_0 cannot both be positive. That proves the claim.

By the claim, P has two **real** roots $w = w_0$ and $w = -\dfrac{1}{w_0}$ for each given h, whenever $w_0 \neq 0$, i.e., whenever $(2t-2) h^2 + (s+2-t) h - s \neq 0$(note that $s - 1 \neq 0$). Of course this just reflects the fact that one can rotate the coordinates axes by α or by $\alpha - \dfrac{\pi}{2}$ and obtain the same axes of the ellipse. The LHS of (31), with $k = L(h)$, factors into $-\dfrac{1}{4}\dfrac{s\left(1+w^2\right)^2 (s-1+t)}{w^2 \left(s-wt+w\right)^2 \left(s-1-wt\right)^2 (s-1)} P(w,h)$. Thus (30) and (31) hold simultaneously for the same h, k, and w if and only if $P(w,h) = 0$ and $k = L(h)$. Since $w \in G$, $m_{j,\alpha}^2 - m_{i,\alpha}^2 \neq 0$ for $i \neq j$. By Theorem 8, (28) and (29) hold simultaneously for the same h_α, k_α, and w if and only if (25) has a solution, with $N = 4$. Then, by Theorem 7, part (ii), (25) has a solution, with $N = 4$, if and only if

$$(33) \qquad S_{ij} = S_{lm}, \ T_{ij} = T_{lm} \text{ for any distinct } i, j, l, m \in \{1, 2, 3, 4\}$$

Of course, (28) and (29) are equivalent to (30) and (31) in xy coordinates. Now an ellipse exists tangent to all four lines if and only if the same ellipse can be found

12

which is tangent to $L_1, L_2,$ and L_4, and to $L_2, L_3,$ and L_4. Thus Theorem 7 and Theorem 8 imply that an ellipse exists tangent to all four lines if and only if there are $w \geq 0$ and h such that $P(w, h) = 0$, $S_{ij} > 0$, and $T_{ij} > 0$ for some $i \neq j$, with $k = L(h)$. It is easiest to work with $i = 1, j = 2$, which is possible except for $w = 0$ or 1. We want to prove that if $(h, k) \in Z$, with $P(w, h) = 0$, then S_{12} and T_{12} are **both positive** if $w \notin \{0, 1\}$. We shall prove that at least one of S_{12} and T_{12} are positive at M_1 and M_2, and that neither can be zero on Z. Let

$$I = \text{open interval with endpoints } \frac{1}{2} \text{ and } \frac{1}{2}s$$

For each given $h \in I$, we shall always assume that w_0 denotes the **nonnegative** root of $P(w, h)$. Then w_0 is a continuous function of h, which we denote by $f(h)$. Letting $w = f(h)$ and $k = L(h)$, S_{ij} and T_{ij} are then functions of h on I. $S_{12}(h)$ and $T_{12}(h)$ are continuous at any point of I if $w = f(h) \neq 0$ or 1. We now show how to extend S_{12} and T_{12} to be continuous at those points as well. First, $(h, k) \in Z$ if and only if $h = \lambda\frac{1}{2} + (1 - \lambda)\frac{1}{2}s, 0 < \lambda < 1$ and $k = L(h)$. We now break the rest of the proof up into two cases:

Case 1: $s \neq t$

$w = 1$ is a solution of $P(w, h) = 0$ if and only if $B(h) = 0$, which holds if and only if $h = \frac{1}{2}$ or $h = \frac{1}{2}\frac{t - s}{s + t - 2}$. If $h = \frac{1}{2}$, then $(h, k) \notin Z$ and $(h, k) \notin X - Y$ (we shall use the latter fact when proving (iii)). If $h = \frac{1}{2}\frac{t - s}{s + t - 2}$, then $k = L(h) = \frac{1}{2}\frac{s - t}{s - 2 + t} = -h$, which implies that h and k cannot both be positive. Hence $w = 1$ **cannot** occur as a solution of $P(w, h) = 0$ for $(h, k) \in Z \cup X - Y$. However, $P(0, h_0)$ can equal 0 for $h_0 \in I$ and certain values of s and t. This is not a problem since, for general h and k, $S_{12} = \frac{k^2w^2 - h^2}{w^2 - 1}$ and $T_{12} = \frac{h^2w^2 - k^2}{w^2 - 1}, w \notin \{0, 1\}$. Thus for *any* fixed h and k, $\lim_{w \to 0} S_{12} = h^2$ and $\lim_{w \to 0} T_{12} = k^2$. S_{12} and T_{12} are then continuous at h_0 if we define, with $k = L(h)$, $S_{12}(h_0) = h_0^2$ and $T_{12}(h) = (L(h_0))^2$. It is also possible that as $h \to h_0 \in I$, the positive root of $P(w, h)$ approaches ∞. Since $\lim_{w \to \infty} S_{12} = k^2$ and $\lim_{w \to \infty} T_{12} = h^2$, defining, with $k = L(h)$, $S_{12}(h_0) = (L(h_0))^2$ and $T_{12}(h_0) = h_0^2$ makes S_{12} and T_{12} continuous at h_0 in that case.

Case 2: $s = t$

In this case the line L is $y = x$, which contains one of the diagonals. The proof is very similar, but simpler, than the proof above for $s \neq t$. Either $(2t - 2)h^2 + 2h - t = 0$, which gives an inscribed circle, or $w = \pm 1$ and $h = k$ can take on any value between $\frac{1}{2}$ and $\frac{1}{2}t$.

Thus we have proven that S_{12} and T_{12} are continuous at any point of I. Now consider the endpoints of I.

● If $h = \frac{1}{2}s$, then $P(w, h) = -(s - 1)^2(ws + t)(s - tw) = 0 \Leftrightarrow w = \frac{s}{t} \neq 1$ since $s \neq t$. If $w = \frac{s}{t}$, then $S_{12} = 0$ and $T_{12} = \frac{1}{4}t^2 + \frac{1}{4}s^2$, and thus S_{12} and T_{12} are continuous and nonnegative at $\frac{1}{2}s$.

- If $h = \dfrac{1}{2}$, then $P(w,h) = -2(w^2 - 1)(s-1)^2 = 0 \Leftrightarrow w = 1$ since $s \neq 1$. S_{12} and T_{12} are undefined when $w = 1$. However, if $w = 1$ and $h = \dfrac{1}{2}$, then $S_{13} = \dfrac{1}{2}$ and $T_{13} = 0$. By (33), this implies that $\lim\limits_{h \to 1/2} S_{12}(h) = \dfrac{1}{2}$ and $\lim\limits_{h \to 1/2} T_{12}(h) = 0$. Thus defining $S_{12}\left(\dfrac{1}{2}\right) = \dfrac{1}{2}$ and $T_{12}\left(\dfrac{1}{2}\right) = 0$ extends S_{12} and T_{12} to be continuous and nonnegative at $\dfrac{1}{2}$.

Thus S_{12} and T_{12} are continuous(or can be extended to be continuous) on the closure of I, and nonnegative at the endpoints of I.

Claim: $S_{12}(h)$ and $T_{12}(h)$ cannot equal 0 for $h \in I$.

Proof of Claim: We can assume that $w \neq 1$ since we have shown that $w = 1$ **cannot** occur as a solution of $P(w,h) = 0$ for $h \in I$. If $P(0,h) = 0$, then $S_{12}(h)$ and $T_{12}(h)$ cannot equal 0 since $h^2 \neq 0$, $L^2(h) \neq 0$ on I. So assume also that $w \neq 0$. Then $S_{12} = \dfrac{k^2 w^2 - h^2}{w^2 - 1} = 0$ if and only if $h = kw (h \neq -kw$ since $h > 0, k > 0)$. If $h = kw$ along with $k = L(h)$, then $h = \dfrac{1}{2} w \dfrac{s - t}{s - 1 - (t-1)w}$ if $w \neq \dfrac{s-1}{t-1}$, which implies that $P(w,h) = -2(w^2 - 1)(s-1)^2 \dfrac{s - tw}{s - 1 - (t-1)w}$, which equals 0 if and only if $w = \dfrac{s}{t}$, which implies that $h = \dfrac{1}{2} s \notin I$. If $h = kw$ along with $k = L(h)$ and $w = \dfrac{s-1}{t-1}$, then $h = \dfrac{1}{2} \dfrac{s - t + 2h(t-1)}{t-1}$, which has no solution since $s - t \neq 0$. $T_{12} = 0$ if and only if $k = wh$. If $k = wh$ along with $k = L(h)$, then $h = \dfrac{1}{2} \dfrac{s - t}{w(s-1) - (t-1)}$ if $w \neq \dfrac{t-1}{s-1}$. This implies that

$$P(w,h) = -2(w+1)(w-1)^2(s-1)^2 \dfrac{(s^2 - s)w + t - t^2}{(w(s-1) - (t-1))^2} = 0 \text{ if and only if}$$

$w = \dfrac{t(t-1)}{s(s-1)}$, which implies that $h = -\dfrac{1}{2} \dfrac{s}{t-1}$. Now $h > 0 \Rightarrow t < 1$ and $w \geq 0 \Rightarrow s < 1$. Also, $(h,k) \in Z$ if and only if $h = \lambda \dfrac{1}{2} + (1 - \lambda)\dfrac{1}{2} s, 0 < \lambda < 1$ and $k = L(h)$. Thus $-\dfrac{1}{2} \dfrac{s}{t-1} = \lambda \dfrac{1}{2} + (1 - \lambda)\dfrac{1}{2} s \Rightarrow \lambda = \dfrac{st}{(t-1)(s-1)}$. Since $s + t \geq 1$, $t \geq 1 - s$ and $1 - t \leq s \Rightarrow \lambda = \dfrac{s}{1-s} \dfrac{t}{1-t} \geq \dfrac{s}{1-s} \dfrac{1-s}{s} = 1$, which implies that $h \notin I$. If $k = wh$, along with $k = L(h)$ and $w = \dfrac{t-1}{s-1}$, then again there is no solution since $s - t \neq 0$. That proves the claim.

Since $S_{12}(h)$ and $T_{12}(h)$ are nonnegative at the endpoints of I, positive at at least one of the endpoints of I, and nonzero on the interior of I, by the Intermediate Value Theorem $S_{12}(h) > 0$ and $T_{12}(h) > 0$ when $h \in I$. Now let $H = \{h \in I : f(h) \in G\}$. $(-\infty, \infty) - G$ is a finite set and $P(w,h) = A(h)(w^2 + C(h)w - 1)$, where $C(h)$ is a nontrivial rational function. Thus $P(w_0, h_0) = 0$ if and only if $C(h_0) = \dfrac{1}{w_0} - w_0$, and by the definition of f, $w_0 = f(h_0)$. It then follows easily that $f^{-1}\{(-\infty, \infty) - G\}$ is

also a finite set, which implies that $I-H$ is a finite set. We have proven that if $h \in H$ and $k = L(h)$, then there is an ellipse with equation $\dfrac{(x_\alpha - h_\alpha)^2}{a^2} + \dfrac{(y_\alpha - k_\alpha)^2}{b^2} = 1$ which is tangent to each of the $L_j, j = 1, 2, 3, 4$, where $a^2 = S_{12}(h)$ and $b^2 = T_{12}(h)$. Since $S_{12}(h)$ and $T_{12}(h)$ are both positive on $int(I)$, if $h_0 \in I-H$, one can obtain an ellipse with center $(h_0, L(h_0))$ by taking a limit of the ellipses obtained for $h \in H$. That proves that if $(h, k) \in Z$, then there is an ellipse inscribed in R and with center (h, k).

Rest of the proof of (ii) and (iii)

Note that $(h, k) \in X \Rightarrow h, k > 0$ and that $\{h : (h, k) \in X - Y\}$ consists of two disjoint open intervals, $J_1 \cup J_2$. The particular endpoints of X depend on whether $s > 1, s < 1, t > s$, etc.

Claim: $S_{12}(h)$ and $T_{12}(h)$ cannot equal 0 for $h \in J_1 \cup J_2$.

Proof of Claim: The proof follows exactly as in the proof above that $S_{12}(h)$ and $T_{12}(h)$ cannot equal 0 for $h \in I$, except for showing that $T_{12}(h) \neq 0$ when $w \neq \dfrac{t-1}{s-1}$, $h = \dfrac{1}{2}\dfrac{s}{1-t}$, and $s, t < 1$. We omit the proof when $s = t$ and consider the following two cases.

Case 1: $s < t$

Then $L(x)$ intersects ∂R in the lines L_2 and L_4, $J_1 = \left(0, \dfrac{1}{2}s\right)$, and

$J_2 = \left(\dfrac{1}{2}, \dfrac{1}{2}s + \dfrac{1}{2}t\right)$. Now $\dfrac{1}{2}s + \dfrac{1}{2}t < \dfrac{1}{2}\dfrac{s}{1-t}$ since $s + t > 1$, which implies that $h = \dfrac{1}{2}\dfrac{s}{1-t} \notin J_1 \cup J_2$ since $\dfrac{1}{2}s + \dfrac{1}{2}t$ is the largest value of $h \in J_1 \cup J_2$.

Case 2: $s > t$

Then $L(x)$ intersects ∂R in the lines L_1 and L_3, $J_1 = \left(\dfrac{1}{2}\dfrac{t-s}{t-1}, \dfrac{1}{2}s\right)$, and

$J_2 = \left(\dfrac{1}{2}, \dfrac{1}{2}s\dfrac{s-2+t}{t-1}\right)$. Again, $s + t > 1$ implies that $\dfrac{1}{2}s\dfrac{s-2+t}{t-1} < \dfrac{1}{2}\dfrac{s}{1-t}$, which implies that $h = \dfrac{1}{2}\dfrac{s}{1-t} \notin J_1 \cup J_2$ since $\dfrac{1}{2}s\dfrac{s-2+t}{t-1}$ is the largest value of $h \in J_1 \cup J_2$. That proves the claim.

We want to show that $S_{12}(h)$ and $T_{12}(h)$ change sign at $h = \dfrac{1}{2}s$ and at $h = \dfrac{1}{2}$, respectively. Recall that $w = f(h) \Leftrightarrow P(w, h) = A(h)w^2 + B(h)w - A(h) = 0$ and $w \geq 0$, where $A(h) = 2(s-1)\left((2t-2)h^2 + (s+2-t)h - s\right)$ and $B(h) = (1-2h)(s-t)\left((2s-4+2t)h + s - t\right)$. Thus implicit differentiation gives $w' = \dfrac{dw}{dh} = -\dfrac{A'(h)w^2 + B'(h)w - A'(h)}{2wA(h) + B(h)}$. Assume throughout that $k = L(h)$. Now suppose that $S'_{12}(h) = 0$. We shall derive a contradiction. Since $S_{12} = \dfrac{k^2w^2 - h^2}{w^2 - 1}$,

$$(34) \qquad (h^2 - k^2)ww' + (kk'w^2 - h)(w^2 - 1) = 0$$

where $k' = \dfrac{dk}{dh} = L'(h) = \dfrac{t-1}{s-1}$. First, if $h = \dfrac{1}{2}s$, then $w = \dfrac{s}{t} \Rightarrow \dfrac{dw}{dh} = 2(s-t)\dfrac{s^2 - 2s + t^2 - 2t}{t^2(s-1)(s^2+t^2)}$, and (34) becomes $w(2(s-t)\frac{s^2-2s+t^2-2t}{t^2(s-1)(s^2+t^2)})(h^2 - k^2) +$

15

$(w^2-1)(k(\frac{t-1}{s-1})w^2-h) = -(s+t)^2\,(s-t)^2\,\dfrac{s}{t^3\,(s^2+t^2)\,(s-1)} = 0$, which it cannot

since $s \neq t$. Thus $S'_{12}(\frac{1}{2}s) \neq 0$, which implies that $S_{12}(h)$ changes sign at $h = \dfrac{1}{2}s$.

Second, if $h = \dfrac{1}{2}$, then $w = 1$, and $T_{12}(h)$ is undefined when $w = 1$. However,

consider $T'_{12}(h) = \dfrac{(w^2-1)(w^2h - kk') + ww'k^2}{(w^2-1)^2}$. Now $w'(\frac{1}{2}) = -\dfrac{B'(\frac{1}{2})}{2A(\frac{1}{2}) + B(\frac{1}{2})} =$

$-2\dfrac{s-t}{s-1}$, which implies that $\displaystyle\lim_{h \to 1/2, w \to 1}(w^2-1)(w^2h - kk') + ww'k^2 = \dfrac{1}{4}w'(\frac{1}{2}) =$

$\dfrac{1}{2}\dfrac{t-s}{s-1} \neq 0$. Thus $T'_{12}(h)$ has the same sign on either side of $h = \dfrac{1}{2}$, which implies

that $T_{12}(h)$ also changes sign at $h = \dfrac{1}{2}$. Since $S_{12}(\frac{1}{2}s) = T_{12}(\frac{1}{2}) = 0$, $S_{12}(\frac{1}{2}) > 0,$,
$T_{12}(\frac{1}{2}s) > 0$, and $S_{12}(h), T_{12}(h) > 0$ on I, by the claim above and the Intermediate
Value Theorem, $S_{12}(h)T_{12}(h) < 0$ on $J_1 \cup J_2$. Let $J = \{h \in J_1 \cup J_2 : f(h) \in G\}$.
We have shown that there is a hyperbola with center (h, k) tangent to each of the
L_j if $h \in J$. Again one can use a limiting argument, as earlier, if $h \notin J$. That
proves that if $(h, k) \in X - Y$, then there is a hyperbola with center (h, k) tangent
to each of the L_j. To finish the proof of (ii) and (iii): In the proof of (ii) given
above, look at the **non-positive** roots w of $P(w, h)$ instead. Everything follows
in the same way. Thus, if $h \in I$, then $S_{ij}(h) > 0$ and $T_{ij}(h) > 0$ for either choice
of the root w. Thus there cannot be a hyperbola with center $(h, k) \in Z$ which is
tangent to each of the L_j. Similarly, in the proof just given that if $(h, k) \in X - Y$,
then there is a hyperbola with center (h, k) tangent to each of the L_j, again look
at the non-positive roots w of $P(w, h)$. If $h \in J_1 \cup J_2$, then $S_{ij}(h)T_{ij}(h) < 0$, which
implies that if $(h, k) \in X - Y$, then there cannot be an ellipse inscribed in R and
with center (h, k).

Remark. The fact that if $(h, k) \in X - Y$, then there cannot be an ellipse in-
scribed in R and with center (h, k) follows from the result in [1] mentioned earlier.
However, we wanted to give a self contained proof which does not use orthogonal
projections.

It is possible that one is just given the four lines L_j, $j = 1, 2, 3, 4$ and not the
polygon R of which they form the boundary. One still might want to know if there
is some ellipse tangent to the given lines, and to characterize the locus of centers of
ellipses tangent to the given lines. The following proposition gives a partial answer.

Proposition 2. Let L_1, L_2, L_3, L_4 be four given lines in the xy plane, such that
no three of the L_j are concurrent. Suppose also that one of the following holds:
(i) No **two** of the L_j are parallel, or
(ii) Exactly two of the L_j are parallel, and the intersection point of the other two
lines does not lie between the two parallel lines.
Then the L_j form the boundary of a four sided convex polygon R.
Proof. (i) Pick a line L. The other lines intersect L at three distinct points since
no three lines have a common intersection point. Let M be the line which inter-
sects L between the other two intersection points. The interior of the triangle T
formed by the three lines not equal to M is cut by M. The two regions into which
M divides T are each convex, since they are the intersections of convex regions(a

16

triangle and a half plane). One of these regions is R.

(ii) Suppose that L_1 and L_2 are parallel and let P_{ij} = point of intersection of L_i and L_j, $(i,j) \neq (1,2)$. Let R be the polygon with vertices P_{13}, P_{14}, P_{23}, and P_{24}. Since P_{34} does not lie between L_1 and L_2, it follows easily that R is a four sided convex polygon. ∎

Theorem 11 then gives

Corollary 2. If L_1, L_2, L_3, L_4 satisfy (i) or (ii) of Proposition 2, then there is an ellipse, E, tangent to each of the L_j, and the center of E must lie on the line thru the midpoints of the diagonals of R.

§4. Three Given Tangents

The rest of the paper is a modification and simplification of results which appeared in [3]. It also contains corrections for several errors in the original version.

Throughout, given $L_1, ..., L_N$, $\Re$ denotes the set of admissible centers, i.e., the set of all (h, k) such that the **non-rotated** ellipse, $\dfrac{(x-h)^2}{a^2} + \dfrac{(y-k)^2}{b^2} = 1$, is tangent to each of the L_j. For convenience, we use the following notation from (16) for $\alpha = 0$. For given m_i, b_i, m_j, and b_j:

$$S_{ij} = \frac{b_j^2 - b_i^2}{m_j^2 - m_i^2}, T_{ij} = \frac{b_i^2 m_j^2 - b_j^2 m_i^2}{m_j^2 - m_i^2}$$

We want to characterize $\Re$ when $N = 3$ and also give an explicit formula for E. Several cases must be considered depending upon whether $m_i^2 = m_j^2$ and/or $m_i = m_j$ for some $i \neq j$. In each case the admissible centers lie on a hyperbola or a straight line(a degenerate hyperbola). The precise curve is obtained by finding conditions on the coefficient matrix of the linear system (12) with $N = 3$. If L_i and L_j are not parallel, we let

(35) $$(x_l, y_l) = \left(\frac{c_j - c_i}{m_i - m_j}, \frac{m_i c_j - m_j c_i}{m_i - m_j} \right)$$

$i \neq l \neq j$, denote their point of intersection.

§4.1 No two of the tangents have slopes equal in absolute value

We first state our results when none of the L_j is horizontal or vertical.

Theorem 12. Let L_1, L_2, L_3 be distinct, non-concurrent, and non–vertical lines with equations $y = L_j(x) = m_j x + c_j$, $j = 1, 2, 3$. Assume that $i \neq j \Rightarrow m_i^2 \neq m_j^2$ and let $D = \prod_{j>i}(m_j - m_i)$, $M = \begin{pmatrix} m_1 & 1 & c_1 \\ m_2 & 1 & c_2 \\ m_3 & 1 & c_3 \end{pmatrix}$, $a_1 = \begin{vmatrix} 1 & m_1^2 & m_1 c_1 \\ 1 & m_2^2 & m_2 c_2 \\ 1 & m_3^2 & m_3 c_3 \end{vmatrix}$, $a_2 = -\begin{vmatrix} 1 & m_1^2 & m_1 \\ 1 & m_2^2 & m_2 \\ 1 & m_3^2 & m_3 \end{vmatrix}$, $p_3(h) = \prod_{j=1}^{3}(h - x_j)$, $p_1(h) = h + \dfrac{a_2}{D}$, $q_3(k) = \prod_{j=1}^{3}(k - y_j)$, $q_1(k) = k + \dfrac{a_1}{D}$, $C = -\dfrac{|M|^2}{2D^2} \prod_{j>i}(m_j + m_i)$. Let γ be the curve with equation

(36) $$p_1(h)q_1(k) = C$$

17

(i) Then

$$(37) \qquad \Re = \left\{ (h,k) \in \gamma : \frac{p_3(h)}{p_1(h)} > 0 \text{ and } \frac{q_3(k)}{q_1(k)} > 0 \right\}$$

For each $(h,k) \in \Re$, there is a unique ellipse $E : \dfrac{(x-h)^2}{a^2} + \dfrac{(y-k)^2}{b^2} = 1$ which is tangent to each of the L_j, with $a^2 = \dfrac{p_3(h)}{p_1(h)}$ and $b^2 = \dfrac{q_3(k)}{q_1(k)}$.

(ii) Write equation (36) in the form $k = f(h)$ or $h = g(k)$.

(a) Suppose that $m_3 \neq 0$, let $w_j = g(y_j)$, $j = 1,2,3$, and define the cubic polynomial

$$r_3(h) = -2 \frac{x_2 - x_3}{m_3 - m_2} \prod_{j=1}^{3} m_j \prod_{j=1}^{3} (h - w_j)$$

Then

$$(38) \qquad \Re = \left\{ (h, f(h)) : \frac{p_3(h)}{p_1(h)} > 0 \text{ and } r_3(h) > 0 \right\}$$

with a^2 as in (i) and $b^2 = \dfrac{r_3(h)}{(p_1(h))^2}$.

(b) Suppose that $m_3 = 0$. Then

$$(39) \qquad \Re = \left\{ (h,k) \in \gamma : \frac{p_3(h)}{p_1(h)} > 0 \text{ and } h \neq \frac{1}{2}(x_1 + x_2) \right\}$$

with a^2 as in (i) and $b^2 = (f(h) - c_3)^2$

(iii) Also, given any $0 \leq e_0 < 1$, there is an $(h,k) \in \Re$ such that E has eccentricity e_0.

Proof. Note that $\text{rank}(M) \geq 2$. If $|M| = 0$, then $\text{rank}(M) = 2 = \text{rank}\begin{pmatrix} m_1 & 1 \\ m_2 & 1 \\ m_3 & 1 \end{pmatrix}$,

which would imply that the system of equations $m_j x + c_j = y, j = 1,2,3$ has a solution (x,y). Since we assumed that the L_j are **not** concurrent, $|M| \neq 0$. This implies that $C \neq 0$. Since $|M| = (m_l - m_i)(m_j - m_i)(x_j - x_l)$ for any distinct $\{i,j,l\} \subset \{1,2,3\}$,

$$(40) \qquad x_i \neq x_j \text{ for } i \neq j$$

It is also useful to note that

$$(41) \qquad |M| = -c_2 m_3 + c_2 m_1 + c_1 m_3 + c_3 m_2 - c_3 m_1 - c_1 m_2 \neq 0$$

Given (h,k), write L_j in the form $y - k = m_j(x - h) + b_j$, $j = 1,2,3$. By Theorem 2 with $N = 3$, there is an ellipse, with center (h,k), tangent to **all three** lines if and only if

$$(42) \qquad \begin{aligned} m_1^2 u + v &= b_1^2 \\ m_2^2 u + v &= b_2^2 \\ m_3^2 u + v &= b_3^2 \end{aligned}$$

18

has a positive solution (u, v). Since $\operatorname{rank}\begin{pmatrix} m_1^2 & 1 \\ m_2^2 & 1 \\ m_3^2 & 1 \end{pmatrix} = 2$, $\operatorname{rank}\begin{pmatrix} m_1^2 & 1 & b_1^2 \\ m_2^2 & 1 & b_2^2 \\ m_3^2 & 1 & b_3^2 \end{pmatrix} \geq 2$,

and thus (42) has a solution(not necessarily positive) if and only if $\begin{vmatrix} m_1^2 & 1 & b_1^2 \\ m_2^2 & 1 & b_2^2 \\ m_3^2 & 1 & b_3^2 \end{vmatrix} =$ 0, which gives

$$(43) \qquad (m_3^2 - m_2^2)b_1^2 - (m_3^2 - m_1^2)b_2^2 + (m_2^2 - m_1^2)b_3^2 = 0$$

By Theorem 2 again, if (43) holds, then the solution of (42) is unique and is given by

$$(44) \qquad u = S_{12} = S_{23} = S_{13}$$

and

$$(45) \qquad v = T_{12} = T_{23} = T_{13}$$

Hence, by Theorem 2, with $N = 3$,

$$(46) \qquad S_{12} > 0 \text{ and } T_{12} > 0$$

and (43) are necessary and sufficient conditions for the existence of an ellipse E

tangent to all three lines. Using (8), (43) becomes $\begin{vmatrix} m_1^2 & (m_1 h + c_1 - k)^2 & 1 \\ m_2^2 & (m_2 h + c_2 - k)^2 & 1 \\ m_3^2 & (m_3 h + c_3 - k)^2 & 1 \end{vmatrix} = 0.$

Multiplying column 1 by $-h^2$ and adding to column 2 yields $\begin{vmatrix} m_1^2 & 2m_1 h(c_1 - k) + (c_1 - k)^2 & 1 \\ m_2^2 & 2m_2 h(c_2 - k) + (c_2 - k)^2 & 1 \\ m_3^2 & 2m_3 h(c_3 - k) + (c_3 - k)^2 & 1 \end{vmatrix} =$

0, which is equivalent to (36). Solving (36) for k and for h, respectively, yields

$$(47) \qquad k = f(h) = \frac{C}{p_1(h)} - \frac{a_1}{D}$$

and

$$(48) \qquad h = g(k) = \frac{C}{q_1(k)} - \frac{a_2}{D}$$

It is easy to show that, for any distinct $\{i, j, l\} \subset \{1, 2, 3\}$,

$$(49) \qquad Dx_j + a_2 = (m_i + m_l)|M|$$

and

$$(50) \qquad Dy_j + a_1 = -m_j(m_i + m_l)|M|$$

19

By (40),(49), and (50), $Dx_l + a_2 \neq 0$ and $Dy_l + a_1 \neq 0$ for any l. Hence by (47) and (48), $v_j = f(x_j)$ and $w_j = g(y_j)$ are each *finite* . By (8), $S_{12} = p(h, k)$, where p is a polynomial which is monic and quadratic in h, and linear in k. Also by (8),

$$(51) \qquad b_j^2 - b_i^2 = (L_j(h) - T_i(h)) \, (L_j(h) + T_i(h) - 2k)$$

Thus $h = x_3 \Rightarrow L_2(h) = L_1(h) \Rightarrow b_2^2 - b_1^2 = 0 \Rightarrow p(x_3, k) = 0$ for any k. Now write L_j in the form $x - h = \dfrac{1}{m_j}(y - k) - \dfrac{b_j}{m_j}$. Substituting $\dfrac{1}{m_j}$ for m_j and

$-\dfrac{b_j}{m_j}$ for b_j in S_{12} yields T_{12}. By interchanging h and k, this easily implies that $T_{12} = q(h, k)$, where q is a polynomial which is monic and quadratic in k, and linear in h. Also, $q(h, y_3) = 0$ for any h. Finally, by (44) and (45), $p(x_j, k) = q(h, y_j) = 0$ for any h and k, and for $j = 1, 2, 3$. For $(h, k) \in \gamma$, $p(h, k) = p(h, f(h)) = \dfrac{p_3(h)}{p_1(h)}$, where p_3 is a monic polynomial of degree ≤ 3 and $p_1(h) = h + \dfrac{a_2}{D}$, by (47). $p(x_j, f(x_j)) = 0$ since $p(x_j, k) = 0$ for any k, which implies that $p_3(h) = \prod_{j=1}^{3}(h - x_j)$. Similarly, for $(h, k) \in \gamma$, $q(h, k) = q(g(k), k) = \dfrac{q_3(k)}{q_1(k)}$, where q_3 is a monic polynomial of degree ≤ 3 and $q_1(k) = k + \dfrac{a_1}{D}$, by (48). $q(g(y_j), y_j) = 0$ since $q(h, y_j) = 0$ for any h, which implies that $q_3(k) = \prod_{j=1}^{3}(k - y_j)$. Since $S_{12} = \dfrac{p_3(h)}{p_1(h)}$ and $T_{12} = \dfrac{q_3(k)}{q_1(k)}$, that proves (i). Substituting $h = g(k)$, one can write $\dfrac{p_3(h)}{p_1(h)} = \dfrac{\prod_{j=1}^{3}(g(k) - x_j)}{g(k) + \frac{a_2}{D}}$. By (49), $\prod_{j=1}^{3}(Dx_j + a_2) = |M|^3 \prod_{j>i}(m_j + m_i)$. Using $f(x_j) = v_j$,

it is not hard to show that $g(k) - x_j = -\dfrac{(Dx_j + a_2)(k - v_j)}{Dk + a_1} \Rightarrow \prod_{j=1}^{3}(g(k) - x_j) =$

$-\dfrac{\prod_{j=1}^{3}(Dx_j + a_2)}{(Dk + a_1)^3} \prod_{j=1}^{3}(k - v_j) = -|M|^3 \dfrac{\prod_{j>i}(m_j + m_i)}{(Dk + a_1)^3} \prod_{j=1}^{3}(k - v_j)$. Finally, it follows

easily that $g(k) + \dfrac{a_2}{D} = |M|^2 \dfrac{\prod_{j>i}(m_j + m_i)}{-2D(Dk + a_1)}$. Putting this altogether, and using

$\dfrac{|M|}{D} = \dfrac{x_2 - x_3}{m_3 - m_2}$, one obtains $\dfrac{p_3(h)}{p_1(h)} = 2 \dfrac{x_2 - x_3}{m_3 - m_2} \dfrac{\prod_{j=1}^{3}(k - v_j)}{(k + \frac{a_1}{D})^2} = \dfrac{s_3(k)}{(k + \frac{a_1}{D})^2}$, where

$s_3(k) = 2 \dfrac{x_2 - x_3}{m_3 - m_2} \prod_{j=1}^{3}(k - v_j)$. $\dfrac{p_3(h)}{p_1(h)}$ is positive, on γ, precisely when $s_3(k) > 0$

since $k + \dfrac{a_1}{D} = 0$ cannot yield a point on γ. Substituting $k = f(h)$, (50), and arguing

as above, one can also show that $\dfrac{q_3(k)}{q_1(k)} = -\dfrac{x_2 - x_3}{m_3 - m_2} \prod_{j=1}^{3} m_j \dfrac{\prod_{j=1}^{3}(h - w_j)}{(h + \frac{a_2}{D})^2}$, which is

20

positive, on γ, precisely when $r_3(h) > 0$ since $h + \dfrac{a_2}{D} = 0$ cannot yield a point on γ. Hence

(52) $$\Re = \{(h,k) \in \gamma : r_3(h) > 0 \text{ and } s_3(k) > 0\}$$

Note that $\Re \neq \emptyset$ since the incenter of T is admissible. One could also prove directly that $\Re$ is nonempty. The *uniqueness* follows from Theorem 1. Since $\dfrac{q_3(f(h))}{q_1(f(h))} = \dfrac{r_3(h)}{(p_1(h))^2}$, (38) follows from (52). That proves (ii)(a).

We now prove that there is an $(h,k) \in \Re$ such that E has eccentricity e_0, with $m_3 \neq 0$. Using (35), it follows easily that for any set of distinct $i,j,l \in \{1,2,3\}$,
$$r_3(x_i) = \frac{1}{8}(m_j + m_l)^2 \frac{(m_j - m_i)^2(m_l - m_i)^2(x_j - x_l)^4}{(m_j - m_l)^4}, \text{ which implies that}$$

(53) $$r_3(x_i) > 0 \text{ for any } i$$

and $r_3\left(-\dfrac{a_2}{D}\right) = \dfrac{1}{8}(m_1 + m_2)^2 (x_3 - x_2)^4 (m_1 + m_3)^2 \dfrac{(m_3 + m_2)^2}{(m_3 - m_2)^4}$, which implies that

(54) $$r_3\left(-\frac{a_2}{D}\right) > 0$$

Let $0 < c \leq 1$ be given. $\dfrac{a^2}{b^2} = c \Rightarrow \dfrac{p_1(h)p_3(h)}{r_3(h)} = c$, which holds if and only if $E(h) \equiv p_1(h)p_3(h) - cr_3(h) = 0$, $r_3(h) \neq 0$. By (53) and (54), $E(x_j) = -cr_3(x_j) < 0$ and $E\left(-\dfrac{a_2}{D}\right) = -cr_3\left(-\dfrac{a_2}{D}\right) < 0$. Let $x_{\max} = \max\{x_1, x_2, x_3, -a_2/D\}$. Then $E(x_{\max}) < 0$, and since $\lim\limits_{h \to \infty} E(h) = \infty$, $E(h_0) = 0$ for some $h_0 > x_{\max}$. Since $p_1(h_0)p_3(h_0) > 0$ it follows that $r_3(h_0) \neq 0$ and $\dfrac{p_1(h_0)p_3(h_0)}{r_3(h_0)} = c > 0$ implies that $r_3(h_0) > 0$. Thus $(h_0, f(h_0)) \in \Re$ by (38), which implies, upon letting $a^2 = \dfrac{p_3(h_0)}{p_1(h_0)}$ and $b^2 = \dfrac{r_3(h_0)}{(p_1(h_0))^2}$, that the equation $1 - \dfrac{a^2}{b^2} = e_0^2$, $0 \leq e_0 < 1$ always has a solution. To prove (ii)(b), if $m_3 = 0$ then it still follows that $S_{12} = \dfrac{p_3(h)}{p_1(h)}$. However, $y_1 = y_2 = c_3$, and $T_{12} = \dfrac{q_3(k)}{q_1(k)}$, where $q_3(k) = (k - c_3)^2(k - y_3)$. Since $\dfrac{a_1}{D} = \dfrac{m_1c_2 - m_2c_1}{m_2 - m_1} = -y_3$, $\dfrac{q_3(k)}{q_1(k)} = (k - c_3)^2 \Rightarrow T_{12} = \dfrac{q_3(f(h))}{q_1(f(h))} = (k - c_3)^2 > 0$ when $k \neq c_3$. Now $k \neq c_3$ if and only if $h \neq g(c_3) = \dfrac{m_1(c_3 - c_2) + m_2(c_3 - c_1)}{2m_1m_2} = \dfrac{1}{2}(x_1 + x_2)$. That proves (39). Again, the *uniqueness* follows from Theorem 1. The proof that there is an $(h,k) \in \Re$ such that E has eccentricity e_0 is similar to the proof above when $m_3 \neq 0$ and we omit it. ∎

§4.1 One of the Tangents is Vertical

Theorem 13. Let L_1 and L_2 be distinct, non-concurrent, and non–vertical lines with equations $y = L_j(x) = m_j x + c_j$, $j = 1, 2$, and assume that $0 \neq m_1^2 \neq m_2^2$. Let L_3 be the vertical line with equation $x = c_3$, and let γ be the curve with equation $(h - x_3)(k - a_1) = -\dfrac{1}{2}(m_1 + m_2)(c_3 - x_3)^2$, where $a_1 = L_2(c_3) + L_1(c_3) - y_3$. Let $q_3(k) = \displaystyle\prod_{j=1}^{3}(k - y_j), q_1(k) = m_1^2(k - a_1)$. Then

(i) $\Re = \left\{ (h, k) \in \gamma : h \neq c_3 \text{ and } \dfrac{q_3(k)}{q_1(k)} > 0 \right\}$. For each $(h, k) \in \Re$, there is a unique ellipse $E : \dfrac{(x - h)^2}{a^2} + \dfrac{(y - k)^2}{b^2} = 1$ which is tangent to each of the L_j, with $a^2 = (h - c_3)^2$ and $b^2 = \dfrac{q_3(k)}{q_1(k)}$.

(ii) Also, given any $0 \leq e_0 < 1$, there is an $(h, k) \in \Re$ such that E has eccentricity e_0.

Proof. Given $C = (h, k)$, write L_j in the form $y - k = m_j(x - h) + b_j$, $j = 1, 2$, and write L_3 in the form $x - h = b_3$. Arguing as earlier, a necessary condition for E to be tangent to L_1 and L_2 is that (7) has the unique positive solution (a^2, b^2) which satisfies (6). Also, a necessary condition for E to be tangent to the line $x = c_3$ is that $a \pm h = c_3 \Rightarrow a^2 = (c_3 \pm h)^2 = b_3^2 > 0 \Rightarrow h \neq c_3$. Thus $S_{12} = b_3^2 \Rightarrow b_2^2 - b_1^2 - (m_2^2 - m_1^2)(h - c_3)^2 = 0 \Rightarrow -2(m_2 - m_1)hk - 2(c_2 - c_1)k + 2(m_2 c_2 - m_1 c_1 + c_3(m_2^2 - m_1^2))h + c_2^2 - c_1^2 - c_3^2(m_2^2 - m_1^2) = 0$

$\Rightarrow hk - \dfrac{c_1 - c_2}{m_2 - m_1}k - \dfrac{m_2 c_2 - m_1 c_1 + c_3(m_2^2 - m_1^2)}{m_2 - m_1}h - \dfrac{c_2^2 - c_1^2 - c_3^2(m_2^2 - m_1^2)}{2(m_2 - m_1)} = 0.$

Now $\dfrac{m_2 c_2 - m_1 c_1 + c_3(m_2^2 - m_1^2)}{m_2 - m_1} = -m_1 x_3 + c_2 + c_3(m_1 + m_2) = L_2(c_3) + L_1(c_3) -$

$L_1(x_3) = a_1$, and thus we have $hk - x_3 k - a_1 h - a_3 = 0 \Rightarrow (h - x_3)(k - a_1) = a_1 x_3 + a_3 = \dfrac{m_2 c_2 - m_1 c_1 + c_3(m_2^2 - m_1^2)}{m_2 - m_1}\dfrac{c_1 - c_2}{m_2 - m_1} + \dfrac{c_2^2 - c_1^2 - c_3^2(m_2^2 - m_1^2)}{2(m_2 - m_1)} =$

$-\dfrac{1}{2}(m_1 + m_2)\dfrac{(-c_1 + c_2 + (m_2 - m_1)c_3)^2}{(m_2 - m_1)^2} = -\dfrac{1}{2}(m_1 + m_2)(c_3 - x_3)^2$, which gives

the curve γ. $a^2 = b_3^2 \Rightarrow b^2 = b_1^2 - m_1^2 a^2 = b_1^2 - m_1^2 b_3^2 > 0 \Rightarrow \dfrac{b_1^2}{m_1^2} > b_3^2 \Rightarrow p(h) \equiv$

$\dfrac{(m_1 h + c_1 - k)^2}{m_1^2} - (h - c_3)^2 > 0.$ Solving $S_{12} - (h - c_3)^2 = 0$ for h gives $h =$

$\dfrac{1}{2}\dfrac{(2c_2 - 2c_1)k - c_2^2 + c_1^2 + c_3^2(m_2^2 - m_1^2)}{(m_1 - m_2)k + m_2 c_2 - m_1 c_1 + c_3(m_2^2 - m_1^2)}.$ Substituting into $p(h)$ yields $q(k) =$

0, where $q(k) = (c_1 + m_1 c_3 - k)(c_2 - k + m_2 c_3)\dfrac{(m_2 - m_1)k + m_1 c_2 - m_2 c_1}{m_1^2((m_2 - m_1)k - (m_2 c_2 - m_1 c_1 + c_3(m_2^2 - m_1^2)))}.$

Thus $q(k) = \dfrac{q_3(k)}{q_1(k)}$, where $q_3(k) = \displaystyle\prod_{j=1}^{3}(k - y_j)$ and $q_1(k) = m_1^2(k - \dfrac{m_2 c_2 - m_1 c_1 + c_3(m_2^2 - m_1^2)}{m_2 - m_1}) =$

$m_1^2(k - (-m_1 x_3 + c_2 + c_3(m_1 + m_2))) = m_1^2(k - a_1).$ That implies that $\Re \subset$

$\{(h, k) \in \gamma : h \neq c_3 \text{ and } \dfrac{q_3(k)}{q_1(k)} > 0\}.$ Now if $h \neq c_3$ and $\dfrac{q_3(k)}{q_1(k)} > 0$, then

letting $a^2 = (h - c_3)^2$ and $b^2 = \dfrac{q_3(k)}{q_1(k)}$ and basically reversing the steps above,

$\dfrac{(x - h)^2}{a^2} + \dfrac{(y - k)^2}{b^2} = 1$ is tangent to each of the L_j, $j = 1, 2, 3$. That proves (i).
We omit the proof of (ii). ∎

§4.2 Two of the tangents have slopes equal in absolute value

In this section we assume that $m_1^2 = m_2^2 \neq m_3^2$. Given $C = (h, k)$, write L_j in the form $y - k = m_j(x - h) + b_j$, $j = 1, 2, 3$. (42) now becomes

$$(55) \qquad\qquad\qquad m_1^2 u + v = b_1^2$$
$$m_1^2 u + v = b_2^2$$
$$m_3^2 u + v = b_3^2$$

Since rank $\begin{pmatrix} m_1^2 & 1 \\ m_1^2 & 1 \\ m_3^2 & 1 \end{pmatrix} = 2$, rank $\begin{pmatrix} m_1^2 & 1 & b_1^2 \\ m_1^2 & 1 & b_2^2 \\ m_3^2 & 1 & b_3^2 \end{pmatrix} \geq 2$, and $\begin{vmatrix} m_1^2 & 1 & b_1^2 \\ m_1^2 & 1 & b_2^2 \\ m_3^2 & 1 & b_3^2 \end{vmatrix} = (m_3^2 - m_1^2)(b_2^2 - b_1^2) = $

0 if and only if $b_1^2 = b_2^2$, (55) has a solution if and only if $b_1^2 = b_2^2$. The unique solution is

$$(56) \qquad\qquad\qquad u = S_{23} = S_{13}$$

and

$$(57) \qquad\qquad\qquad v = T_{23} = T_{13}$$

If (56) and (57) are positive, then we let $a^2 = u$ and $b^2 = v$ to obtain the equation of the required ellipse. The condition $b_1^2 = b_2^2$ implies $(m_1 h + c_1 - k)^2 = (m_2 h + c_2 - k)^2$, which implies (using $m_1^2 = m_2^2$) that

$$(58) \qquad 2(m_2 - m_1)hk + 2(m_1 c_1 - m_2 c_2)h + 2(c_2 - c_1)k + c_1^2 - c_2^2 = 0$$

Our next theorem covers the case when $m_2 = -m_1$.

Theorem 14. Let L_1, L_2, L_3 be distinct, non-concurrent, and non–vertical lines with equations $y = L_j(x) = m_j x + c_j$, $j = 1, 2, 3$. Assume that $m_2 = -m_1 \neq 0$ and that $m_1^2 \neq m_3^2$. Let $Q(h) = (h - x_1)(h - x_2)$, $L_1(k) = -2 \dfrac{x_3 - x_2}{m_3 + m_1}\left(k - \dfrac{m_3 x_3 + c_3 + y_3}{2}\right)$, and $P(k) = (k - y_1)(k - y_2)$.

(a) $m_3 \neq 0$: Let $L_2(h) = -2 \dfrac{m_1 m_3}{m_3 + m_1}(y_3 - y_2)\left(h - \dfrac{m_3 x_3 + y_3 - c_3}{2m_3}\right)$. Then $\Re = \Re_1 \cup \Re_2$, where $\Re_1 = \{(x_3, k) : L_1(k) > 0 \text{ and } P(k) > 0\}$ and $\Re_2 = \{(h, y_3) : L_2(h) > 0 \text{ and } Q(h) > 0\}$. If $(h, k) \in \Re$, there is a unique ellipse $E : \dfrac{(x - h)^2}{a^2} + \dfrac{(y - k)^2}{b^2} = 1$ which is tangent to each of the L_j, with $a^2 = \begin{cases} L_1(k) \text{ if } (h, k) \in \Re_1 \\ Q(h) \text{ if } (h, k) \in \Re_2 \end{cases}$

and $b^2 = \begin{cases} P(k) \text{ if } (h,k) \in \Re_1 \\ L_2(h) \text{ if } (h,k) \in \Re_2 \end{cases}$

(b) $m_3 = 0$: Then $\Re = \Re_1 \cup \Re_2$, where $\Re_1 = \{(x_3,k) : L_1(k) > 0 \text{ and } k \neq c_3\}$, $\Re_2 = \{(h,y_3) : h < \min(x_1,x_2) \text{ or } \max(x_1,x_2) < h\}$. Again E is unique, with a^2 as in (a), and $b^2 = \begin{cases} (k-c_3)^2 \text{ if } (h,k) \in \Re_1 \\ (y_3-c_3)^2 \text{ if } (h,k) \in \Re_2 \end{cases}$

(c) Also, for (a) or (b) above, given any $0 \leq e_0 < 1$, there is an $(h,k) \in \Re$ such that E has eccentricity e_0.

Proof. Since $m_2 = -m_1$, $x_1 = \dfrac{c_2 - c_3}{m_1 + m_3}$, $x_2 = \dfrac{c_3 - c_1}{m_1 - m_3}$, $y_1 = \dfrac{m_1 c_3 + m_3 c_2}{m_3 + m_1}$,

$y_2 = \dfrac{m_1 c_3 - m_3 c_1}{m_1 - m_3}$, $x_3 = \dfrac{c_2 - c_1}{2m_1}$, $y_3 = \dfrac{c_1 + c_2}{2}$, and (58) reduces to $-4m_1 hk +$
$2m_1(c_1+c_2)h + 2(c_2-c_1)k + c_1^2 - c_2^2 = 0 \Rightarrow -(2k - c_1 - c_2)(2m_1 h - c_2 + c_1) = 0 \Rightarrow$
$(h-x_3)(k-y_3) = 0 \Rightarrow k = y_3$ or $h = x_3$. One can also obtain this equation by letting
$m_2 = -m_1$ in (36). Hence the admissible centers must lie on $\gamma = \{(h,k) : h = x_3 \text{ or } k = y_3\}$. Note that $\dfrac{a_1}{D} = -y_3$, $\dfrac{a_2}{D} = -x_3$, and $h = x_3$ and $k = y_3$ are
just the asymptotes of the hyperbola with equation (36). Since $L_3(x_2) = L_1(x_2)$,
$(L_3(h) - L_1(h))/(m_3 - m_1) = h - x_2$. Write L_j in the form $x = \bar{L}_j(y) = \dfrac{1}{m_j}y - \dfrac{c_j}{m_j}$.
Then $\bar{L}_3(y_2) = \bar{L}_1(y_2) \Rightarrow (\bar{L}_3(k) - \bar{L}_1(k))/(1/m_3 - 1/m_1) = k - y_2$. By (51),
$S_{13} = (h - x_2)(L_3(h) + L_1(h) - 2k)/(m_3 + m_1)$. The equation of $\bar{L}_j$ can also be
written as $x - h = \dfrac{1}{m_j}(y - k) - \dfrac{b_j}{m_j}$, $m_j \neq 0$. Substituting $\dfrac{1}{m_j}$ for m_j and $-\dfrac{b_j}{m_j}$ for
b_j in S_{13} yields T_{13}. Interchanging h and k then gives $T_{13} = (\bar{L}_3(k) - \bar{L}_1(k))(\bar{L}_3(k) +$
$\bar{L}_1(k) - 2h)/(1/m_3^2 - 1/m_1^2) = (k - y_2)(\bar{L}_3(k) + \bar{L}_1(k) - 2h)/(1/m_3 + 1/m_1)$ We
must determine the points on γ where S_{13} and T_{13} are **both positive** . We have
two cases to consider.

Case 1: $h = x_3$
Then $S_{13} = (x_3 - x_2)(L_3(x_3) + L_1(x_3) - 2k)/(m_3 + m_1)$
$= -2(x_3 - x_2)(k - \frac{L_3(x_3)+y_3}{2}) =$

(59) $\qquad\qquad -2\dfrac{x_3 - x_2}{m_3 + m_1}\left(k - \dfrac{m_3 x_3 + c_3 + y_3}{2}\right) = L_1(k)$

Now $\bar{L}_1(y_1) + x_1 = 2x_3$ and $\bar{L}_3(y_1) = x_1 \Rightarrow \bar{L}_3(k) + \bar{L}_1(k) - 2x_3$ vanishes at $k = y_1 \Rightarrow$
$T_{13} = (k - y_2)(\bar{L}_3(k) + \bar{L}_1(k) - 2x_3)/(1/m_3 + 1/m_1) = (k - y_1)(k - y_2) = P(k)$.
Note that if $m_3 = 0$, then $y_1 = y_2 = c_3$ and the above formula for $P(k)$ still holds
since $T_{13} = (k - c_3)^2$. Also, $P(k) = \dfrac{q_3(k)}{q_1(k)}$ from Theorem 12 since $\dfrac{a_1}{D} = -y_3$.

Case 2: $k = y_3$
It also follows easily that $L_3(h) + L_1(h) - 2y_3$ vanishes at $h = x_1$. Then $S_{13} =$
$(h - x_2)(L_3(h) + L_1(h) - 2y_3)/(m_3 + m_1) = (h - x_1)(h - x_2) = Q(h)$. Note that
$Q(h) = \dfrac{p_3(h)}{p_1(h)}$ from Theorem 12 since $\dfrac{a_2}{D} = -x_3$. Now $T_{13} = (y_3 - y_2)(\bar{L}_3(y_3) +$
$\bar{L}_1(y_3) - 2h)/(1/m_3 + 1/m_1) = (y_3 - y_2)(\bar{L}_3(y_3) + x_3 - 2h)/(1/m_3 + 1/m_1) =$

24

$$-2\frac{m_1 m_3}{m_3 + m_1}(y_3 - y_2)(h - \tfrac{\bar{L}_3(y_3) + x_3}{2}) =$$

$$-2\frac{m_1 m_3}{m_3 + m_1}(y_3 - y_2)\left(h - \frac{m_3 x_3 + y_3 - c_3}{2m_3}\right) = L_2(h), m_3 \neq 0$$

If $m_3 = 0$, and $h = x_3$, then $S_{13} = L_1(k)$ as above. $T_{13} = b_3^2 = (L_3(x_3) - k)^2 > 0$ if $k \neq L_3(x_3) = c_3$. If $m_3 = 0$, and $k = y_3$, then $S_{13} = Q(h)$ as above. $T_{13} = b_3^2 = (L_3(h) - y_3)^2 = (c_3 - y_3)^2 > 0$ since if $c_3 = y_3$, then $L_1(x_3) = L_2(x_3) = L_3(x_3) = y_3$, which violates the assumption that the L_j are not concurrent. The uniqueness in each case follows from Theorem 1 since $m_1^2 \neq m_3^2$. That proves (a) and (b). To prove (c): (i) If $h = x_3$, then $\dfrac{b^2}{a^2} = \dfrac{P(k)}{L_1(k)}$. Since $m_2 = -m_1$, by (41) , $|M| = -m_3 c_2 + m_1 c_2 + m_3 c_1 - 2m_1 c_3 + m_1 c_1 \neq 0$. Some algebra shows that $L_1(y_1) = \dfrac{(m_1 c_2 - m_3 c_2 + c_1 m_1 + m_3 c_1 - 2m_1 c_3)^2}{4m_1^2 (m_3 + m_1)^2}$ and $L_1(y_2) = $ $\dfrac{(m_1 c_2 - m_3 c_2 + c_1 m_1 + m_3 c_1 - 2m_1 c_3)^2}{4m_1^2 (m_1 - m_3)^2}$, which implies that $L_1(y_j) > 0, \; j = 1, 2$.

Let $0 < c \leq 1$ be given. Setting $\dfrac{b^2}{a^2} = c$ implies that $\dfrac{P(k)}{L_1(k)} = c$, which holds if and only if $E(k) \equiv P(k) - cL_1(k) = 0$, $L_1(k) \neq 0$. Let $y_{\max} = \max\{y_1, y_2\}$. Since $E(y_j) = -cL_1(y_j) < 0, E(y_{\max}) < 0$, and since $\lim_{k \to \infty} E(k) = \infty$, $E(k_0) = 0$ for some

$k_0 > y_{\max}$. Since $P(k_0) > 0$ it follows that $L_1(k_0) \neq 0$ and $\dfrac{P(k_0)}{L_1(k_0)} = c > 0$ implies that $L_1(k_0) > 0$. Thus $(x_3, k_0) \in \Re$ by (38), and implies, upon letting $b^2 = P(k_0)$ and $a^2 = L_1(k_0)$, that the equation $1 - \dfrac{b^2}{a^2} = e_0^2, 0 \leq e_0 < 1$, always has a solution. (ii) If $k = y_3$, the proof follows in a similar fashion. $\blacksquare$
Our next theorem covers the case when $m_2 = m_1$.

Theorem 15. Let L_1, L_2, L_3 be distinct non–vertical lines with equations $y = L_j(x) = m_j x + c_j$, $j = 1, 2, 3$, and assume that $m_2 = m_1$, with $m_1^2 \neq m_3^2$. Let L be the line with equation $y = L(x) = m_1 x + \dfrac{1}{2}(c_1 + c_2)$. Let $P(h) = \left(\dfrac{m_3 - m_1}{m_3 + m_1}\right)(h - x_1)(h - x_2)$ and $Q(k) = -\left(\dfrac{m_3 - m_1}{m_3 + m_1}\right)(k - y_1)(k - y_2)$.
(i) If $m_1 \neq 0$, then $\Re = \{(h, k) : k = L(h) \text{ with } P(h) > 0 \text{ and } Q(k) > 0\}$.
(ii) If $m_1 = 0$, then $\Re = \left\{(h, \dfrac{1}{2}(c_1 + c_2)) : P(h) > 0\right\}$.

In either case, if $(h, k) \in \Re$, then there is a unique ellipse $E : \dfrac{(x - h)^2}{a^2} + \dfrac{(y - k)^2}{b^2} = 1$ which is tangent to each of the L_j, with $a^2 = P(h)$ and $b^2 = Q(k)$.
(iii) Finally, given any $0 \leq e_0 < 1$, there is an $(h, k) \in \Re$ such that E has eccentricity e_0.
Proof. Note that $c_1 \neq c_2$ since L_1 and L_2 are distinct. Since $m_2 = m_1$, $x_1 = \dfrac{c_3 - c_2}{m_1 - m_3}$, $x_2 = \dfrac{c_3 - c_1}{m_1 - m_3}$, $y_1 = \dfrac{m_1 c_3 - m_3 c_2}{m_1 - m_3}$, $y_2 = \dfrac{m_1 c_3 - m_3 c_1}{m_1 - m_3}$, and (58) re-

duces to $2hm_1(c_1 - c_2) + 2k(c_2 - c_1) + c_1^2 - c_2^2 = 0 \Rightarrow$

(60) $$2hm_1 - 2k + c_1 + c_2 = 0$$

Note that by (60), an admissible center must lie on L, and L is parallel to, and lies exactly halfway between, L_1 and L_2. Solving (60) for k yields $k = m_1 h + \frac{1}{2}(c_1 + c_2)$. Since $L_3(x_2) = L_1(x_2)$, and $L_3(x_2) + L_1(x_2) - 2m_1 x_2 - (c_1 + c_2) = 0$, upon substituting for k it follows that $S_{13} = (L_3(h) - L_1(h))(L_3(h) + L_1(h) - 2m_1 h - (c_1 + c_2))$, which vanishes at x_1 and x_2. Thus

(61) $$S_{13} = \left(\frac{m_3 - m_1}{m_3 + m_1}\right)(h - x_1)(h - x_2) = P(h)$$

Solving (60) for h yields(if $m_1 \neq 0$)

$$h = \frac{2k - (c_1 + c_2)}{2m_1}$$

It also follows easily that, upon substituting for h

(62) $$T_{13} = -\left(\frac{m_3 - m_1}{m_3 + m_1}\right)(k - y_1)(k - y_2) = Q(k)$$

That proves (i). If $m_1 = 0$, then (h, k) lies on the horizontal line with equation $y = \frac{1}{2}(c_1+c_2)$. Since $y_1 = c_2$ and $y_2 = c_1$, $k = \frac{1}{2}(c_1+c_2) \Rightarrow Q(k) = \frac{1}{4}(c_1-c_2)^2 > 0$. Using (61), the set of admissible centers now equals $\{(h, \frac{1}{2}(c_1 + c_2)) : P(h) > 0\}$, which proves (ii). The *uniqueness* follows for each case from Theorem 1 since $m_1^2 \neq m_3^2$. To prove (iii): If $(h, k) \in \gamma$, then $\frac{b^2}{a^2} = \frac{Q(k)}{P(h)} = \frac{Q(L(h))}{P(h)} = \frac{Q(k)}{P(g(k))}$ and $m_1^2 a^2 + b^2 = b_1^2 \Rightarrow m_1^2 P(h) + Q(k) = b_1^2 = (m_1 h + c_1 - L(h)) = \frac{1}{4}(c_1 - c_2)^2$. Letting $k = y_j$ yields

(63) $$P(g(y_j)) = \frac{1}{4}\frac{(c_1 - c_2)^2}{m_1^2} > 0$$

and letting $h = x_j$ yields

(64) $$Q(L(x_j)) = \frac{1}{4}(c_1 - c_2)^2 > 0$$

Case 1: $\frac{m_3 - m_1}{m_3 + m_1} > 0$

Let $0 < c \leq 1$ be given. Setting $\frac{a^2}{b^2} = c$ implies that $\frac{P(h)}{Q(k)} = \frac{P(h)}{Q(L(h))} = c$, which holds if and only if $E(h) \equiv P(h) - cQ(L(h)) = 0$, $Q(L(h)) \neq 0$. Let $x_{\max} =$

26

$\max\{x_1, x_2\}$. Since $E(x_j) = -cQ(L(x_j)) < 0$ by (64) , $E(x_{\max}) < 0$. Since the coefficient of h^2 in $P(h) - cQ(L(h))$ is $\dfrac{m_3 - m_1}{m_3 + m_1} + c\dfrac{m_3 - m_1}{m_3 + m_1}m_1^2$, $\lim\limits_{h \to \infty} E(h) = \infty$. Thus $E(h_0) = 0$ for some $h_0 > x_{\max}$. Since $P(h_0) > 0$ it follows that $Q(L(h_0)) \neq 0$ and $\dfrac{P(h_0)}{Q(L(h_0))} = c > 0$ implies that $Q(L(h_0)) > 0$. Letting $k_0 = L(h_0)$ implies that $(h_0, k_0) \in \Re$ by (38), which implies, upon letting $a^2 = P(h_0)$ and $b^2 = Q(L(h_0))$, that the equation $1 - \dfrac{b^2}{a^2} = e_0^2, 0 \le e_0 < 1$, always has a solution.

Case 2: $\dfrac{m_3 - m_1}{m_3 + m_1} < 0$

Then consider $\dfrac{b^2}{a^2} = \dfrac{Q(k)}{P(h)} = \dfrac{Q(k)}{P(g(k))}$ and the rest of the proof follows in a fashion similar to case 1. ∎

§4.2 All three of the tangents have slopes equal in absolute value
Clearly, if $m_1 = m_2 = m_3$, then there is no ellipse tangent to all of the L_j. Hence we can assume, without loss of generality, that $m_1 = m_2 = -m_3$. In this case the set of admissible centers consists of two points. For each such center, there are infinitely many ellipses tangent to the L_j.

Theorem 16. Let L_j, $j = 1, 2, 3$ be three non–vertical lines with equations $y = m_j x + c_j$, and assume that $m_1 = m_2 = -m_3$. Then $\Re = \{(x_2, y_1), (x_1, y_2)\} = \left\{\left(\dfrac{c_3 - c_2}{2m_1}, \dfrac{c_1 + c_3}{2}\right), \left(\dfrac{c_3 - c_1}{2m_1}, \dfrac{c_2 + c_3}{2}\right)\right\}$. If $(h, k) \in \Re$, the ellipse $\dfrac{(x - h)^2}{a^2} + \dfrac{(y - k)^2}{b^2} = 1$ is tangent to each of the L_j, where a^2 and b^2 are any positive solutions of $a^2 m_1^2 + b^2 = \dfrac{1}{4}(c_1 - c_2)^2$. Finally, given any $0 \le e_0 < 1$ and any $(h, k) \in \Re$, one can choose a^2 and b^2 such that E has eccentricity e_0.
Proof. Given $C = (h, k)$, write L_j in the form $y - k = m_j(x - h) + b_j, j = 1, 2, 3$. Since $m_1^2 = m_2^2 = m_3^2$, (42) has a solution if and only if $b_1^2 = b_2^2 = b_3^2$. The solutions satisfy the one equation

(65) $$m_1^2 u + v = b_1^2$$

If $b_1 \neq 0$, then (65) has infinitely many positive solutions (u, v) and the ellipse $E : \dfrac{(x - h)^2}{a^2} + \dfrac{(y - k)^2}{b^2} = 1$ is tangent to L_1, L_2, and L_3, where $a^2 = u$ and $b^2 = v$. By (8), $b_1^2 = b_2^2$ and $b_1^2 = b_3^2$ imply that $2(m_j - m_1)hk + 2(m_1 c_1 - m_j c_j)h + 2(c_j - c_1)k + c_1^2 - c_j^2 = 0$ for $j = 2, 3$, which yields the two simultaneous equations

$$2hm_1 - 2k + c_1 + c_2 = 0, \ (2k - c_1 - c_3)(2m_1 h - c_3 + c_1) = 0$$

with solutions $(h, k) = \left(\dfrac{c_3 - c_2}{2m_1}, \dfrac{c_1 + c_3}{2}\right) = (x_1, y_2)$ and $\left(\dfrac{c_3 - c_1}{2m_1}, \dfrac{c_2 + c_3}{2}\right) = (x_2, y_1)$. Note that those points are distinct since $c_1 \neq c_2$(else $L_1 = L_2$). It is not

hard to show that $(h, k) = \left(\dfrac{c_3 - c_2}{2m_1}, \dfrac{c_1 + c_3}{2} \right)$ if and only if $b_1 = \dfrac{1}{2}(c_1 - c_2)$, $b_2 = -b_1$, and $b_3 = -b_1$, and $(h, k) = \left(\dfrac{c_3 - c_1}{2m_1}, \dfrac{c_2 + c_3}{2} \right)$ if and only if $b_1 = \dfrac{1}{2}(c_1 - c_2)$, $b_2 = -b_1$, and $b_3 = b_1$. For each choice of (h, k) above, $b_1 \neq 0$ with $b_1^2 = b_2^2 = b_3^2$. As a^2 varies between 0 and $\dfrac{b_1^2}{m_1^2}$, one obtains infinitely many positive solutions a^2, b^2 of the equations in (65), and $\dfrac{a^2}{b^2}$ varies from 0 to ∞. Thus one can also find an ellipse with any preassigned eccentricity. $\blacksquare$

Remark. For three given tangents(no two of which are parallel) there is a very nice result about ellipses inscribed in the triangle, T, formed by the tangents. Let T_M denote the midpoint triangle, that is the triangle whose vertices are the midpoints of the sides of T. Chakerian [1] proved that $\cup_{-\frac{\pi}{2} < \alpha < \frac{\pi}{2}} \Re_\alpha = int(T_M)$. Chakerian uses orthogonal projection to prove this result, methods much different than the ones used in this paper. One can also prove this result using methods similar to the proofs given for four given lines, though the proof is longer and not as concise. However, using our methods one can also show that the union, over α, of the α admissible centers for **hyperbolas** equals $int(T) - \{int(T_M) \cup T_M\}$.
